In 1944, former head of "Rumor Control" for the Massachusetts Committee of Public Safety Robert Knapp defined "rumor" in *Public Opinion Quarterly* as "a proposition for belief of topical reference disseminated without official verification" (p. 22). He described rumors as providing detailed "information" spread by word of mouth that satisfy some emotional or psychological need of a community. It is the "spread by word of mouth" element that imbues the decades-old concept of "rumors" with increasing relevance in today's social media ecosystem. In their prescient 2000 article, Kuklinski et al. argue that the conventional "informed vs. uninformed" dichotomy conflates two very different kinds of uninformed people—those who do not know the facts, on the one hand, and those who believe false information (the "misinformed"), on the other. They called for more research on the causes and consequences of misinformation ("information that is false, but the person who is disseminating it believes that it is true"; Wardle & Derakhshan, 2018, p. 44), pointing to the potential deleterious effects of a misinformed public that is likely to resist facts that contradict their misinformed beliefs. Vraga and Bode (2020) call for a differentiation between information that is *false* and information that is merely *unsubstantiated*, such as operationalizing misinformation as "*information considered incorrect based on the best available evidence from relevant experts at the time*" (p. 138) for example. Such distinctions would take into account the fluid nature of expert consensus, especially from such domains as science and law.

Disinformation, in contrast, is "information that is false, and the person who is disseminating it knows it is false" (Wardle & Derakhshan, 2018). Efforts to spread

information that is knowingly false violate the free will and transparency assumptions at the heart of persuasion theory (see Perloff, 2020). Disinformation is thus more akin to propaganda and deception. Propaganda and persuasion scholars have long recognized that mass media propaganda, absent supplementary interpersonal messaging, was unlikely to persuade audiences (Lazarsfeld & Merton, 1948). Because decentralized social media embed media messaging and user-generated content *within* interpersonal networks, disinformation and other forms of propaganda that are spread through these channels may be at a persuasive advantage (Young & McGregor, 2020). Jamieson (2020) chronicles how Russian propaganda operatives—especially online “trolls”—capitalized on the decentralized and networked logics of Facebook to exploit preexisting cultural cleavages during the 2016 US presidential election. She also illustrates how news organizations, driven by biases toward personalized, conflict-oriented news, legitimized and amplified these disinformation efforts. Munger (2020) argues that economic incentives that drive clickbait media lead to “credibility cascades” that enable misinformation to flourish. Meanwhile Garrett (2017) argues that the threat posed by deliberate politically strategic disinformation campaigns is far greater than the threat posed by the logics of the technologies themselves. He also explores how citizens might use the affordances of social media platforms to increase information accuracy, accountability, and civility.

Yet research on how elite-driven disinformation interacts with media affordances, logics, and economics paints a far clearer picture of democratic harm than of democratic health. Rhetoric scholars have detailed how political elites such as Donald Trump (Mercieca 2018) make strategic use of the affordances of the new media environment to spread falsehoods directly to the public. Using the metaphor of a polluted landscape, Philips and Milner (2021) explore how polluted information such as White supremacist ideology and conspiracy theories have permeated the media landscape and point to the interconnected, intertwined, and deeply networked nature of mis- and disinformation as being particularly pernicious and difficult to combat. Rosenblum and Muirhead (2020) identify a new form of conspiracism borne out of the new media landscape, which they define as conspiracy *without* a theory. “There is no punctilious demand for proofs, no exhaustive amassing of evidence, no dots revealed to form a pattern, no close examination of the operators plotting in the shadows. The new conspiracism dispenses with the burden of explanation. Instead, we have innuendo and verbal gesture . . . What validates the new conspiracism is not evidence but repetition . . . The effect of conspiracist thinking once it ceases to function as any sort of explanation is delegitimation” (p. 3).

Domestic propaganda efforts abound in the new media landscape (Shin et al., 2018), sometimes originating with inaccurate online rumors that resurface repeatedly to an extent that accurate rumors do not. On Twitter, such misinformation is often repackaged and brought back to life strategically by partisan news organizations, hence transforming *misinformation* into *disinformation* (Shin et al., 2018). Moreover, misinformation can spread “farther, faster, deeper, and more broadly than the truth” (Vosoughi et al., 2018, p. 1146; but see Guess et al., 2019 for work that shows that the sharing of misinformation during the 2016 election was rare). Recognition of the potential negative consequences of belief in misinformation and conspiracy theories (Douglas et al., 2019; Kuklinski et al., 2000) has also spurred research that explores the effectiveness of content aimed at combating misinformation, through either inoculation or “prebunking” (Lewandowsky & van der Linden, 2021), refutations from unlikely sources (Berinsky, 2015), or through correcting misinformation

once it has taken hold (e.g., Chan et al., 2017; Garrett et al., 2013; Nyhan et al., 2020; Ophir et al., 2020; Trujillo et al., 2021; Walter et al., 2020; Young et al., 2018)

8. THE “EFFECTS”

Lastly, we review scholarship that demonstrates how the changing media landscape necessitates a reimagining of the effects of political communication, focusing on message processing, cognitive theories of media effects (specifically, agenda-setting), and political polarization.

8.1. Message Processing

Dual-process models of information processing like the Elaboration Likelihood Model (Petty & Cacioppo, 1986) and the Heuristic Systematic Model (Chaiken, 1980) continue to dominate cognitive psychological approaches to political communication processing and effects (for a review of this literature see Jerit & Kam, Chapter 17, this volume). Both models conceptualize individual motivation (see Chen et al., 1999) and ability as the factors that determine whether individuals are thoughtful and analytical as they process information, or if they are guided by heuristic cues, like source credibility (Sundar, 2008), attractiveness, or aesthetic features of the message. The notion that information processing is contingent on an individual's motivation and ability to engage thoughtfully with a message is crucial when considering the effects of political messages embedded within decentralized networked ecosystems that are *also* fragmented and micro-segmented.

Writing in 1995, Negroponte introduced the concepts of “push” and “pull” media to capture the distinction between old broadcast media that were “pushed” out to people versus digital media that people can select and “pull” toward themselves. “Being digital will change the nature of mass media from a process of pushing bits at people to one of allowing people (or their computers) to pull at them,” he wrote (1995, p. 84). Building on the concepts of “push” and “pull” media, Holbert et al. (2010) explicate the implications of digital “pull” media for cognitive processing. They propose that the logics of old mass “push” media were likely to be met by audience members comparatively lower in motivation to process media content (because there was less opportunity for content selection), hence resulting in a greater likelihood of peripheral and heuristic message processing. But with fragmentation, choice, and interpersonally contextualized media experiences, users are guided by a motivation and ability to “pull” relevant, interesting, socially beneficial content toward them. Holbert et al. (2010) argue that this means media content is likely to be engaged with thoughtfully, or centrally, hence resulting in attitudes that are resistant and longer-lasting, or—if scrutiny results in counterargumentation—less attitude change and more message resistance. These dynamics also complicate the historical distinction between media exposure and media attention (Chaffee & Schleuder, 1986; Semetko et al., 1992), as the decision to select and “pull” content toward oneself in a high choice media environment might itself be indicative of interest in and attention to that content.

Since political messaging and news are now embedded within social networks, interpersonal dynamics ought to shape motivation and ability to thoughtfully engage with information content as well. In the context of public opinion toward an unfamiliar issue (nanotechnologies), Ho, Scheufele, and Corley (2013) found that people are mainly guided by heuristic cues when processing news, yet interpersonal communication changes these dynamics. The link between cognitive elaboration and public opinion toward nanotechnologies was contingent on interpersonal communication on the topic. In an examination of how people process and learn from information obtained through news versus through social contacts, Carlson (2019) found people learned more through news—except when the social contact was like-minded and knowledgeable, in which case individuals learned as much through the social contact as they did through news.

Looking at the effects of online comments on news story processing and engagement, message relevance (related to processing motivation) matters. User comments focused on a specific dimension (regionalism) of a news story shape audience recall and persuasion, especially for individuals for whom that dimension (regionalism) is especially salient (e.g., those highest in regional self-identity; Lee et al., 2017). Users' perceptions of the credibility of news stories are also affected by the valence of user comments, especially for users to whom the content is relevant (Winter et al., 2015). Yet, while social media users consider their friends more credible than news organizations in general, they still rate specific news articles as more credible when shared by a news organization than by a friend (Tandoc, 2019).

When it comes to political expression and information sharing decisions in online contexts, experimental work indicates that motivation to thoughtfully process a message might be overshadowed by reputational and social motivations (Winter, 2020). Winter (2020) found that users who anticipated writing on social media about a given news article were more likely to be motivated by impression management than by the quality of the arguments in the article itself. Whereas people express themselves politically online for social and persuasion-related reasons (see Eveland et al., 2011), the effects of political expression on cognitive elaboration and subsequent political participation is contingent on which motivations are guiding them, with persuasion motivations a bigger driver of elaboration and participation (compared to social motivations), mediated by news-seeking behaviors (Yoo et al., 2017).

Finally, the notion that exposure to “pull” media might reflect increased motivation to engage in cognitive elaboration and argument scrutiny may itself be complicated by factors related to the physical technologies themselves. Many users, especially younger users, engage in “second-screen” or “dual-screen” behaviors (see Gil de Zuniga & Liu, 2017), typically involving the use of a smartphone or tablet while (or immediately following) consuming other media, such as television or streaming content (see Nee & Barker, 2020). Such dual-screen activities during news or political debate viewing can increase cognitive load and reduce news processing, recall, and comprehension (Van Cauwenberge et al., 2014). However, research also points to emotional and social benefits of second-screen behaviors, including building feelings of community and learning the opinions of others (Nee & Barker, 2020), as well as political benefits, including seeking additional information, sharing information, and expanding knowledge in ways that fuel further political engagement (Chadwick et al., 2017; Vaccari et al., 2015).

Increased reliance on smartphones, tablets, and computers for news (see Shearer, 2021) has spurred scholars to study the impact of screen size and mobile news features on

cognitive processing, attention, and learning, with disappointing results. Dunaway et al. (2018) demonstrate that although shifts in news norms and production routines for mobile devices might increase access to news, they may also erode regular in-depth engagement with news stories. Their eye-tracking studies illustrate that even when users perceive that they are paying attention to news content on mobile devices, that attention is lower than it is on computers. Additional lab studies reveal that video news, when consumed on mobile devices, elicits lower psychophysiological responses than when consumed on larger screens, hence indicating less cognitive engagement with—and arousal to—news programming on mobile (Dunaway & Soroka, 2021).

8.2. Agenda-Setting Revisited. Again. And Again and Again

The decentralized control of political media, networked logics of digital spaces, and reduced gatekeeping authority of traditional news organizations all change the context within which cognitive theories of media effects occur. Take agenda-setting, for instance. Although we still see evidence of legacy news outlets shaping the agendas of the public (Tran, 2013), agenda-setting effects are far smaller among those who rely on alternative and online information sources (Shehata & Stromback, 2013). Feezell (2018) found that people had their agendas shaped by “incidentally encountered” stories on social media, with the strongest agenda-setting effects found among those lowest in political interest.

Meanwhile, the story-selection decisions of journalists and editors are themselves influenced by online and alternative content as well, as news organizations include stories and events that have circulated through social media and niche outlets (Jacobson, 2013). Gilardi et al. (2022) found that the news’ agenda was set by the social media agenda of politicians and political organizations, and their agendas were, in turn, shaped by the news and by each other. This “intermedia agenda-setting” research (McCombs, 2004), exploring who is setting whose agenda, illustrates that although traditional news is still a dominant setter of the public’s agenda (Djerf-Pierre & Shehata, 2017), Twitter—especially media-related Twitter—helps to set the agenda of mainstream news (Harder et al., 2017; Valenzuela et al., 2017), especially in the context of breaking news stories (Su & Borah, 2019). Additionally, partisan news outlets are driving the agendas of some traditional legacy news outlets (Vargo & Guo, 2017); by covering stories that serve their ideological perspective, they indirectly pressure mainstream outlets to cover those stories as well. These complex reciprocal agenda-setting dynamics have significant consequences, especially if the online content shaping the agenda of a news organization is *false*, something that is particularly likely for partisan news organizations (Guo & Vargo, 2020; Vargo et al., 2018).

Networked and intermedia dynamics permit bottom-up agenda-setting processes that may empower issue publics and activists (Luo, 2014; Su & Hu, 2020). With the public’s agenda constructed through these complex relationships, the nature of Downs (1972) “issue attention cycle” has changed. The “alarmed-discovery” phase that used to catapult the public into action is no longer driven by the media’s agenda alone, but also through interpersonal discussion and mobilization through social media (Zhang et al., 2017). Issue publics mobilized through “hashtag activism” help shape media and policy agendas, framing issues from racial justice (Bonilla & Rosa, 2015; Yang, 2016) to gendered terrorism attacks (Carter Olson, 2016) to sexual harassment (Xiong et al., 2019).

In the largely homogeneous, mass-audience-oriented media system of the 1970s, articulating a distinction between signaling to people what issues to pay attention to versus persuading people to think a certain way made sense. But by 2005, as that distinction was becoming obsolete, McCombs circled back again. “The media not only can be successful in telling us what to think about,” he wrote, “they also can be successful in telling us *how to think about it*” (McCombs, 2004, p. 546). So-called attribute agenda-setting or second-level agenda-setting is similar to framing in that it involves elements of a news story being made more salient in ways that influence how audiences think about the issue (Entman, 1993). With fragmented partisan media outlets reporting on stories in ways that complement their networks’ ideological leanings, attribute agenda-setting (Muddiman et al., 2014) and framing have become an essential part of contemporary media effects research. Recent studies illustrate how partisan news frames shape viewer perceptions of issues ranging from immigration (Gil de Zuniga et al., 2012) to climate change (Feldman et al. 2012), to COVID vaccines (Jamieson & Albarracin, 2020; but see also Trujillo & Motta, 2021 for data from 144 countries indicating that mere internet access itself is related to vaccine hesitancy) to election integrity and voter ID laws (Wilson & Brewer, 2013).

8.3. Political Polarization

The new media landscape is both interpersonal and identity-reinforcing by design. As discussed above, media and political elites and non-elites alike have incentives to create emotion-laden content (whether it be information, misinformation, or disinformation) that taps into the intended audience’s increasingly aligned (Mason 2018) social and political identities. And audiences have a greater ability than ever before to selectively expose themselves to content that meets their informational, entertainment, identity-reinforcing, and/or attitude-reinforcing needs. This perfect storm of content production and content selection is what Slater (2007, 2015) calls a reinforcing media spiral—social identity drives media behaviors in ways that reinforce those identities. The “spiral” aspect of these relationships stems from the recursive dynamics between exposure and polarization that numerous scholars have highlighted (Prior, 2013; Stroud, 2010). Such studies point both to media contributing to polarization, and to polarization-fueling exposure to like-minded media. Given the central role that identity plays in political polarization (Iyengar et al., 2012), recent research has explored the impact of political communication in this new media environment on both attitude and affective polarization (see Tucker et al., 2018, for a comprehensive review of the role that misinformation plays in this process).

With regard to attitude polarization, Song and Boomgaarten (2017) use an agent-based modeling approach to demonstrate the role of interpersonal (dis)agreement in the reinforcing media spiral process, concluding that, “reciprocal dynamics between attitude polarization and attitudinally congruent partisan media exposure over time critically hinge on the attitudinal composition of one’s discussion network and contextual variations in which such media exposure occurs” (p. 18). Feldman et al. (2014) use a two-wave panel study to test the reinforcing spirals model in the context of attitudes about global warming, finding evidence for an “ongoing, reinforcing cycle in which media use influences beliefs, and these beliefs then affect subsequent media use, which, in turn, reinforces beliefs” (p. 603). And Lee et al. (2014) find that the positive relationship between social network homogeneity

and attitude polarization is strongest among people who engage in political discussions more often than those who do not. These polarization effects are also moderated by the variation in affordances of different social media platforms (e.g., Facebook, Twitter, and WhatsApp; Yarachi et al., 2020). In her book, *Niche News*, Stroud (2011) demonstrates how partisan selective exposure, exacerbated by the proliferation of partisan media outlets, can simultaneously increase (not necessarily equitable) political participation *and* contribute to attitude polarization and fragmented interests. Pointing to the potential deleterious effects of this process for democracy, Stroud (2011, p. 10) argues that: “the onslaught of diverse partisan media outlets may undercut the development of common goals . . . Without a shared issue agenda, allocation of limited resources, such as time and money, become more difficult.” Arceneaux and Johnson (2013) argue that some of the polarizing effects demonstrated in this literature are a methodological artifact—experiments that force exposure to pro- or anti-attitudinal content. In a series of innovative experiments, Arceneaux and Johnson (2013) demonstrate that the polarizing effects of exposure to partisan media sources are limited by audience characteristics and the available content choices (i.e., whether people can opt out of news/political content altogether). Prior’s (2013) work indicates that attitude polarization from selective media exposure is limited to those individuals who are highly politically interested and engaged, a subpopulation that is arguably more likely to wield political influence.

Recent research also points to the role of digital algorithms and curated information flows in exacerbating political divisions (Cho et al. 2020). In contrast, Munger and Phillips’ (2022) analysis of right-wing political content on YouTube challenges the notion that algorithms themselves *cause* polarization and/or radicalization. They propose a supply-and-demand framework for analyzing the impact of political content on YouTube. Rather than the supply of right-wing YouTube content turning moderates into radicals (in a top-down, “hypodermic” way), the authors argue for the central role of content demand in this process: “the true threat posed by some right-wing content on YouTube is the capacity for creators to draw communities of committed viewers that mutually create and reinforce radical political canons, including some that promote hatred. There is a cap on how much news media a person can consume in a given day; YouTube has dramatically increased the number of distinct political communities which are able to hit that content cap” (p. 3). Although more research is needed to pin down the precise nature of the causal impact of algorithms, it is clear that dominance of algorithms and curated flows of information in the new media environment necessitate methodological advances that can distinguish the effects of *selective* exposure (demand), on the one hand, and *selected* (e.g., by algorithms) exposure (supply), on the other (Thorson et al., 2019; Thorson & Wells, 2016).

While attitude polarization concerns the shifting of policy positions toward partisan extremes, affective polarization refers to the rise in negative attitudes toward the opposing political party. In the latter context, emerging evidence highlights the role of media exposure, with subtle and contingent effects of media as a function of audience and content characteristics. For example, Druckman et al. (2019) find that the relationship between exposure to partisan incivility and positive affect toward, and trust in, the party of the source of the incivility is moderated by whether the content is pro- or counter-attitudinal; such exposure is depolarizing for in-party members, but polarizing for out-party members. Work by Hasell and Weeks (2016) illustrates the implications of affective polarization beyond mere attitudes, finding that exposure to pro-attitudinal content increases anger toward the opposing party,

which, in turn, increases the likelihood of *sharing* the content. Lelkes, Sood, and Iyengar (2017) find that access to broadband internet increases negative affect toward out-partisans, likely due to the increased exposure to partisan media that broadband affords. In her book, *Frenemies*, Settle (2018) proposes the END framework of social media interaction to conceptualize the political psychological process that exacerbates polarization in this new media landscape. “END refers to the characteristics of a subset of content that circulates in a social media ecosystem: a personalized, quantified blend of politically informative *expression*, *news*, and *discussion* seamlessly interwoven into a wider variety of socially informative content” (p. 50). Using this framework, Settle (2018) illuminates the ways in which even incidental exposure to and interaction with political (and, importantly, *nonpolitical*) content increases identity salience *and* has downstream effects on social inferences and affective polarization. All told, media are implicated in both attitudinal and affective polarization, in complex ways that are contingent on audience psychology and platform characteristics.

9. ADVANCES IN POLITICAL COMMUNICATION RESEARCH METHODS

The changing media landscape has also led to innovations in research methods from ones focused primarily on studying the unidirectional impact of “the”(singular) media on individuals (as individuals) to ones that enable researchers to study the networked, bidirectional, interpersonal, and fragmented nature of political communication causes and effects.”

9.1. New Sampling Platforms

In recent years, scholars have increasingly relied on cheap online participant samples, including Amazon’s Mturk and Prolific, often for experiments, panels, and real-time online experiments (Christenson & Glick, 2013). But reliance on these samples often presents problems related to sample representativeness that pose unique problems for political communication researchers. Mturk samples, for example, tend to lack older participants (see Brewer et al., 2016), and the few older participants they do include are far higher in “digital literacy” (Hargittai, 2002, 2005) than older non-Mturkers. Such self-selection presents generalizability problems when looking at political and communication dynamics that vary with age or digital literacy (Munger et al., 2021), like the susceptibility to—or willingness to share—mis- and disinformation (Guess & Munger, 2020).

9.2. Digital Trace Data

Whereas new technologies gave rise to cheap sampling platforms like Mturk, they also ushered in an era of “big data” and “computational social science” in the field of political communication (Stroud & McGregor, 2018). Digital trace data from social media and other online behaviors has been used to study social networks and political behavior (Zuckerman,

2005), agenda-setting effects (Conway et al., 2015; Neuman et al., 2014), and information flows (Wells & Thorson, 2017). While the potential to study previously unmeasurable phenomena (Watts, 2011) is revolutionary for the field of political communication (Bode, 2018), scholars urge that the temptation to fetishize data over theory should be resisted (Gonzalez-Bailon, 2013). Gonzalez-Bailon reminds us, “Social science has the theoretical tradition to build a context for these data, point to the right mechanisms of the dynamics analyzed, and build credible interpretations—which is as important as having access to vast amounts of information and cutting-edge methods” (p. 159). Combinations of survey research with digital trace data can help center theory within such big data approaches (Choi, 2020; Stier et al., 2020a).

And although social media data accurately predict election outcomes and the results of empirical public opinion surveys (Ceron et al., 2014), recent studies of the users of various tech platforms suggest we should use caution as we consider who these people are and who they are not (Auxier & Anderson, 2021). For example, Pew reports that while 71% of 18–29-year-olds use Instagram and 42% use Twitter, among adults 65 and older, these numbers drop to 13% and 7%, respectively. There are also important racial and ethnic differences, with 46% of Hispanics reporting using WhatsApp, compared to 23% of Black respondents, and 16% of White respondents. Twitter, in particular, is unique in ways that have implications for political communication research, as its users make less money, are less educated, and less likely to live in rural areas compared to non-users (Auxier & Anderson, 2021). Freelon urges scholars to take into account the technical design, terms of service, social context, and potential for misrepresentation introduced by particular platforms as they select digital trace data sources (Freelon, 2018). Through a nuanced understanding of the “patterns and dynamics” underlying trace data (Jungherr, 2015), scholars can contextualize findings in a transparent and meaningful way.

9.3. Automatic Coding Techniques

Advances in computational methods have also opened the doors for large-scale studies of the content of—and trends in—political information and media content (see Grimmer & Stewart, 2013). These include large-scale sentiment analysis to capture the extent of affect in news (Young & Soroka, 2012), the extent of news content on Twitter (Malik & Pfeffer, 2016), the misinformation ecosystem (Vargo et al., 2018), and the content of comments sections on news websites (Muddiman, 2018). As automated big-data approaches to the study of political information increase in number, we again find warnings from those seeking to keep theory at the center of political communication research. Reliance on automated techniques might lack a nuanced understanding of language and cultural symbols. They may also incentivize a “data-mining” approach, where trends are identified first, and post hoc explanations to account for those trends are concocted later. Such warnings include recommendations for the integration of crowd-coding (Haselmayer & Jenny, 2017) and manual coding into computer automated coding techniques (Lewis et al., 2013; Zamith & Lewis, 2015). Whereas some (Pal & Gonawela, 2017) make the case for “a return to small data” in content analysis with the integration of qualitative and interpretive approaches, others implore scholars to return to interpretive, mixed-methods approaches to the study of political communication as a whole to “build theory and analyze social life” (Karpf et al., 2015).

9.4. Measuring Exposure to Political Communication

The most important construct in the field of political communication research is also the most hotly contested: exposure to media content (see de Vreese & Neijens, 2016; Fishbein & Hornik, 2008). People are unreliable reporters of their own media use (see Parry et al., 2021; Prior, 2009b) and tend to overestimate their exposure to programming that they do, indeed, consume (Jurgens et al., 2020; Prior, 2009a). But, the validity of self-reported exposure measures also varies with question wording (see Smith & Neijens, 2011, for a review), with self-reported exposure to specific sources more reliable than general exposure measures (Scharkow, 2019). Self-reported measures are also complicated by the fact that users multitask with media (Foehr, 2006), including engaging in “second-screen” viewing (Van Cauwenberge et al., 2014).

Such issues raise the question of measuring exposure through more “passive” approaches through recording technologies, or digital trace data, as discussed above (de Vreese & Neijens, 2016). Yet, media exposure obtained through tracking devices that users agree to install on their devices is not unbiased either (Jurgens et al., 2020), both in terms of the kind of people who would allow themselves to be tracked in this way, and in the behavioral changes people might make because their media behaviors are being tracked. When comparing self-reported and logged smartphone use in their effects on aspects of social behavior and well-being, Jones-Jang et al. (2020) found that the self-reported measures underestimated the strength of these relationships, hence suggesting that the size of media effects *in reality* might be much larger than self-reports would suggest. Jerit et al. (2016) propose a hybrid “benchmark” approach to compare experimentally manipulated exposure to self-reported exposure, and then examine question-wording options to understand which produces the most “accurate” self-reported measure of exposure.

Media fragmentation increases individuals’ opportunities to selectively choose—or avoid—exposure to media content. But on social media platforms like Facebook, exposure to politically relevant content—just incidentally through our newsfeeds—is shaped by our own behaviors, our friends’ behaviors, and behaviors of news organizations, advertisers, and platform algorithms (Thorson & Wells, 2016). Our exposure behaviors, therefore, are more akin to “exposure opportunities” that are constrained by media context. Thorson et al. (2019) use survey data combined with respondents’ individually downloaded Facebook data archives to mimic Facebook’s understanding of users’ political interest and to capture how Facebook had labeled individuals for advertisers (politically interested or not). Their results show that individuals “algorithmic identity, as categorized by Facebook, has an independent relationship to content exposure above and beyond user-reported levels of topical interest” (p. 193). If Facebook decides you are politically interested, you get more political content in your feed. If not, you do not. Such constraints in media choice must be factored into conceptualizations of “media exposure” and into theoretical models of effects.

10. CONCLUSION

We argue in this chapter that the conventional theories and processes at the core of the field of political communication are rooted in assumptions that no longer hold and contexts that

no longer exist. Today's media are decentralized, interpersonal, horizontal, and networked, a combination that has sweeping implications for the ways that individuals use, interact with, and are used *by* media. We focused here on two main changes in media experiences that upend assumptions of the field: (1) individuals today encounter socially and interpersonally contextualized messaging, and (2) this is occurring within a system predicated on the economics and logics of micro-segmentation. We assert that these are *qualitative* shifts. In other words, this is not simply a story about more outlets, a blurring of entertainment and information, or more partisan media content. Instead, this is a story about how shifts in fundamental aspects of message production, dissemination, consumption, and selection change the essence of the theoretical mechanisms at play within the field of political communication. And these new mechanisms are highly social, interpersonal, psychologically contingent, and mediated. They will require creative integration of political psychology—from the study of the drivers of message development and dissemination, to research on the nature of message selection, processing, and effects.

We use Lassewell's (1948) "who said what to whom, with what effect" model to illuminate the ways in which changes in the logics and economics of media and digital technologies disrupt traditional political communication theory. Political communication is no longer unidirectional and vertical. The *who* is now virtually everyone (and, with algorithms, perhaps even "everything"), upending the notion of "gatekeepers" and broadening our conceptualization of the channels of political communication. The *who* is also acting in a socially networked, group-identity-driven context in which the traditional message receivers (the *whom*) are interconnected with others who might also be message producers and message sharers (the old *who*). Meanwhile, the social media landscape provides these individuals with more opportunities to be active and effective *seekers* of messaging. Yet these seemingly empowering characteristics of digital technologies also facilitate and incentivize the strategic curation and packaging of content by message producers (at both the elite and mass level); message producers seeking to attract, engage, persuade, and mobilize their intended audience. Hence, today's *whom* has both *more choice* to select content that suits their needs and goals and, counterintuitively, *less agency* (due to strategic message development, algorithms, and curated information flows), leading to concerns about echo chambers and polarization, most notably on the margins where the effects of extremism are the most devastating.

Because the economics of media systems have adapted to the changing *who* and *whom*, the content of political communication (the *what*) has also changed in its composition, including the proliferation of hyper-emotional and uncivil content, increasing not only misinformation and disinformation, but also interpersonal political communication and socially networked political communication experiences. With these evolving *whos*, *whats*, and *whoms* come advances in our understanding of the complex mechanisms at play within and between our communication experiences (like the Reinforcing Media Spirals Model, or Curated Information Flows), which allow us to rethink the types of politically relevant *effects* we might find (e.g., message processing, agenda-setting, or political polarization).

Today's media ecosystem creates new and expanded opportunities for the role of political psychology within the field of political communication: in media selection behaviors, in the moderation and mediation of effects processes, and in the anticipation of individual psychology by message producers and disseminators. As these processes become known

to—and anticipated by—message producers, they inform the deliberate construction and curation of the very media content people encounter. This is what we mean when we say audience psychology is now “baked into” media products and messaging strategies. As such, the political communication of tomorrow must tackle thorny questions about what these changes in the information environment mean for the role that political psychology plays in the study of political communication. What are the effects of the fact that psychology is now baked into message construction and dissemination to attract audiences by exploiting socio-political identities and emotions? And how, and under what conditions, does the interpersonally networked media environment increase identity salience (e.g., through selective or incidental exposure), incentivize the production and sharing of mis- and disinformation, and further fragment and polarizes society, on the one hand, or (and) open up new avenues for political consciousness-raising, political participation, and collective action, on the other?

CHAPTER 17

THE PSYCHOLOGICAL AND SOCIAL FOUNDATIONS OF IDEOLOGICAL BELIEF SYSTEMS

CHRISTOPHER M. FEDERICO AND ARIEL MALKA

1. IDEOLOGY AND POLITICAL PSYCHOLOGY

THE concept of ideology plays a central role in both normative and empirical understandings of political life. The importance of ideology derives in large part from the inherent complexity of politics, which invariably involves disputes about issues, values, and even understandings of reality in a variety of domains. Ideologies offer one way of managing this complexity. By providing leaders and citizens alike with comprehensive, organized frameworks for making sense of politics, ideologies supply political actors with ready-made judgments about the state of the world and many issues at once, while also furnishing an overarching narrative about *why* various political concerns fit together (Converse, 1964; Feldman, 2013; Lipset, 1960). Ideologies also explain and justify political reality. They provide rationales for why, and in what ways, the *status quo* should be preserved or changed (Bobbio, 1996; Jost et al., 2009; Sidanius & Pratto, 1999). In short, ideologies confer structure, meaning, and cohesive rationales for action in a domain that would otherwise be intractably complicated.

Not surprisingly, ideologies especially animate the outlook of those most deeply invested in the business of politics. For example, ideologies have often received their most articulate and systematic expression in the work of political philosophers, pundits, and intellectuals, who have offered competing analyses of how and why societies function and how they should ideally be organized (Heywood, 2007; Laponce, 1981; Noel, 2014). Closer to the day-to-day conduct of political affairs, political parties and their leaders (“elites” in the argot of political science) rely on ideological abstractions to organize their platforms and structure political competition (Benoit & Laver, 2006; Lijphart, 1990; Lipset & Rokkan, 1967; Sniderman & Bullock, 2004). Though the ideological work of party officials may not be as ornate as that of philosophers, it plays an essential role in lending coherence to party programs that span what would otherwise be hard-to-connect issue domains (Federico, 2021). Ideologies, in the practical partisan sense, allow a simpler choice between

a manageable number of—oftentimes, two—“crowning postures,” rather than leaving citizens to make a multitude of judgments about specific issues (Converse, 1964; Zaller, 1992; see also Downs, 1957).

Though the normative significance of ideology and its importance to elite political discourse is clear, social scientists have disagreed about whether ideology plays a meaningful role in organizing the preferences of citizens in the mass public. Much of this disagreement stems from differences in opinion about what, precisely, it means to make use of ideology in one’s political reasoning and behavior. For example, abundant evidence suggests that the average citizen does not consistently apply ideological principles in everyday political judgments or behavior, and in many cases citizens do not hold the kind of stable political preferences that ideology would imply (Converse, 1964, 2000; Federico, 2020; Kalmoe, 2020; Kinder & Kalmoe, 2017). But this characterization of the mass public as “innocent of ideology” has not gone uncontested. Other scholars, for example, argue that the apparent absence of ideological sophistication among everyday citizens is an artifact of poor measurement (e.g., Achen, 1975). Others note that diverse attitudes may be functionally interconnected not by consistent application of abstract principles, but by service to a common set of underlying psychological motives (e.g., Jost, 2006). Still others emphasize identity processes as the mechanism that provides structural coherence to ideological outlooks among ordinary people (e.g., Federico & Malka, 2018).

Though thinkers from a variety of disciplines have contributed useful analyses of ideology as a phenomenon (Heywood, 2007; Laponce, 1981), political psychology offers a unique, important perspective on the foundations, functions, and sweep of ideologies. In particular, political psychology provides crucial insights about how political preferences are ideologically organized and what processes give rise to the kinds of ideological belief systems we observe in various political contexts. Moreover, research on the psychological bases of ideology has shed light on the psychological needs, traits, and motives that attract individuals to one ideology or another—and how the relationships between psychological variables and political preferences vary across issue domains, persons, and situations.

In this chapter, we provide a broad overview of research on the political psychology of ideological belief systems. In the first section, we review work on the nature, structure, and psychological foundations of ideology. We begin by addressing basic questions of how to define and conceptualize ideology, and how it might be differentiated from other kinds of political orientations. We then discuss the most important ideological construct examined by political psychologists: the left-right continuum (Jost et al., 2009, 2013). While noting the significance of the left-right dimension, we discuss ways in which its role in shaping preferences in mass publics is conditional and review a growing body of evidence that ideology may be multidimensional rather than unidimensional in its psychological structure. Next, we cover research on the dispositional predictors of ideology, focusing on the core finding that individuals who score high (versus low) on measures of psychological rigidity and threat sensitivity tend to hold right-wing (versus left-wing) preferences within important political domains. We also discuss the boundary conditions of the dispositional model, noting that the relationship between psychological variables and political preferences is moderated to a substantial extent, and in theoretically coherent ways, by factors such as issue domain, political engagement, and national context. We then review research suggesting that individuals on both the left and right may rigidly defend their convictions,

despite the tendency for conservative identifiers to score higher on dispositional indices of psychological rigidity.

In the second section of the chapter, we review theory and evidence regarding the social nature of ideology, with a particular focus on the social mechanisms that hold various elements of ideological belief systems together. We discuss various core social motives that lead people to adopt and act in accordance with different ideological identities and belief systems, including motives for bonding and intimacy with close others, motives to act in accordance with politically relevant social identities, and motives to defer to cues provided by trusted leaders. We also describe how the force provided by these social motives may encourage polarization and the sorting of electorates into ideologically disparate partisan camps. In turn, in the third section of the chapter, we discuss how ideological polarization and sorting may have feedback effects on other social divides and on psychological dispositions themselves. This is followed by the fifth section, in which we describe the implications of the ideological phenomena reviewed in this chapter for contemporary efforts to understand challenges to the integrity of democratic institutions.

In the final section, we conclude by summarizing and highlighting two key take-home messages of our review. The first is that links between psychological attributes and subsets of ideological attitudes sometimes appear to be organic and directly functional but other times appear to be conditional on how the relevant attitudes are packaged with other attitudes into socially constructed ideologies (Federico & Malka, 2018). Attention to this matter is important for understanding the psychological organization and societal implications of ideology. Second, we conclude that the social motives that give ideology its “absorptive” power—its ability to draw substantively diverse attitudes into ideological alignment—are also likely, within polarized contexts, to induce people to adopt non-political identities and self-perceptions that are congruent with ideological stereotypes (Bakker et al., 2021; Boston et al., 2018; Egan, 2020; Margolis, 2018a). How this phenomenon might perpetuate and aggravate polarization, and ultimately threaten democratic stability, is an important matter for researchers to attend to.

2. THE NATURE, STRUCTURE, AND MOTIVATIONAL UNDERPINNINGS OF IDEOLOGY

2.1. What Is Ideology?

We begin with a simple definitional question: what is ideology? Social scientists have pondered this question extensively, and in some ways there are as many definitions as there are scholars. However, a few key definitions cover the most important points (see Jost et al., 2009, p. 309). For example, political scientists Robert Erikson and Kent Tedin (2003) define ideology as a “set of beliefs about the proper order of society and how it can be achieved” (p. 64). More elaborately, Denzau and North (1994/2000) describe ideologies as “mental models” that “provide an interpretation of the environment and a prescription as to how that environment should be structured” (p. 24). In an effort at synthesis, Federico (2020)

identifies three crucial defining features that are common to most definitions of ideology that political psychologists rely on: (1) ideologies are *belief systems* that tie an ideological identity together with specific attitudes, beliefs, and values in a functionally interdependent way across multiple domains (e.g., Brandt & Sleegers, 2021); (2) ideologies are *socially shared* among members of a group and reflect the life circumstances of people living in a specific social context; and (3) ideologies are *both descriptive and prescriptive*, in that they explain why society *is the way it is* and make normative statements about what society *should* ideally be like.

Though most conceptualizations of ideology share these basic features, they sometimes differ in the extent to which they approach ideology from a more functional perspective versus a “critical” one (Jost et al., 2009, 2013). The functional perspective usually takes a “value-neutral” tone, focusing on the organizational and interpretive role of political belief systems (e.g., Converse, 1964; Knight, 1999; see also Brandt & Sleegers, 2021). This approach derives variously from sociological functionalism and from formal treatments of ideology in political science that emphasize the role of ideology in simplifying political choices and systems of party competition (e.g., Downs, 1957; Hinich & Munger, 1994; see also Lipset, 1960; Lijphart, 1990; Benoit & Laver, 2006; Lipset & Rokken, 1967). In contrast, the critical perspective focuses more on the “system-justifying” role of ideologies—that is, on how ideologies may hide, excuse, or legitimize oppressive social arrangements. This approach descends in part from the classical Marxist view of ideology, which observed “the ideas of the ruling class are in every epoch the ruling ideas” (Marx & Engels, 1846/1970). Continuing in this vein, later theorists spoke similarly of ideology as a kind of “cultural hegemony” (Gramsci, 1971) or as “systematically distorted communication” (Habermas, 1989). In contemporary political psychology, the critical perspective is incorporated most strongly into system justification theory (Jost, 2020) and social dominance theory (Sidanius & Pratto, 1999), which argue that members of subordinate social groups will be less likely to challenge systems of stratification or pursue the interest of their own group if they endorse beliefs suggesting that the unequal status quo is “fair” or morally justified. Often, the ideologies described by these models are narrower in nature than the broad worldviews that the belief systems perspective focuses on (e.g., the Protestant work ethic as a justification for economic inequality, as opposed to a broader conservative ideology covering both economics and other domains).

The core claims of these two perspectives on ideology do not mutually exclude each other; ideologies can be both belief systems *and* tools for justifying existing states of affairs. Though we touch on both treatments of ideology in this chapter, we focus on ideologies as generalized, interlinked belief systems (e.g., Converse, 1964, 2000; Eagly & Chaiken, 1993). We do so in part to differentiate ideologies from other attitudes, values, and beliefs that may justify the status quo in a specific fashion but do not tie together positions across multiple issue domains in an interlocking way. But more importantly, we do so in order to clearly differentiate belief systems *per se* from the underlying psychological motives or institutional or group-interest functions that belief systems might sometimes serve. In other words, we do not make any restrictive assumption that a belief system only counts as “ideology” if it serves a system- or group-interest-justifying purpose.

Ideologies, then, are broad overarching structures comprised of multiple idea-elements that are socially shared and anchored in identity. Political psychologists have in turn identified several core components of these structures, ranging from issue positions at

the most concrete level to higher-order values and principles at the most abstract level (Feldman, 2013; Goren, 2012; Peffley & Hurwitz, 1985). A few key distinctions are especially important here. First, public-opinion research frequently distinguishes between ideology in the “symbolic” or “philosophical” sense and ideology in the “operational” sense (Ellis & Stimson, 2012; Free & Cantril, 1967; Stimson, 2004). Symbolic ideology refers to identification with a particular ideological category (e.g., conservative or liberal; Ellis & Stimson, 2012), whereas philosophical ideology refers to an abstract posture regarding social life (e.g., a libertarian preference for smaller government or a conservative preference for a more cautious orientation toward social change; Free & Cantril, 1967). In contrast, operational ideology refers to the general tilt of one’s issue preferences, averaging across specific policy choices (e.g., whether one prefers more or less government intervention in the economy across various issues; Stimson, 2004). Importantly, these facets of ideology do not always hang together. For example, in the aggregate, Americans are simultaneously more likely to identify symbolically as “conservatives” but operationally prefer the “liberal” option of greater government spending across issues; indeed, a large proportion of individual citizens who identify as conservatives also favor greater spending (Ellis & Stimson, 2012; see also Gidron, 2022). Moreover, not all of these facets are equally central to individuals’ belief systems. In this respect, the symbolic components of ideology (e.g., ideological identifications) are more strongly linked than operational issue positions with a larger number of belief-system elements and with actual voting behavior (e.g., Brandt et al., 2019; Brandt & Slegers, 2021).

Second, researchers have distinguished between the *discursive superstructure* and *motivational substructure* of ideologies (Jost et al., 2009; see also Federico, 2021; Federico & Malka, 2018). The discursive superstructure of an ideology is its ideational content, consisting of the specific issue attitudes, values, and beliefs that go along with an ideological identity in a particular political context; it is the symbolic and positional content of an ideology. The motivational substructure of an ideology is the set of psychological motives and characteristics that attract people to one ideological posture or another (e.g., to the political left versus the political right). These include traits that reliably incline people to the left or right in particular domains; for instance, as we note in more detail below, strong needs for security and certainty tend to predict conservative positions in several (but not all) issue domains and contexts (e.g., Jost et al., 2009). In general, discursive superstructures are socially constructed networks of commitments, forged most strongly by the creative work of intellectuals and political elites (Converse, 1964; Noel, 2014). As such, they vary from one context to the next. The psychological variables that comprise the motivational substructure are more universal. For example, they include personality traits that are relatively similar across human populations (e.g., Hibbing et al., 2014; Mondak, 2010). That said, the dispositions that make up the motivational substructure vary in their relationship with ideological preferences as a function of issue domain, political engagement, and contextual factors, as we shall see. For example, while those high (versus low) in needs for certainty are more attracted to conservative (versus liberal) positions on several issues, this relationship breaks down when the certainty-providing meaning of these conservative positions is not clear (e.g., Johnston et al., 2017).

2.2. A Core Ideological Construct: The Left-Right Dimension

One of the most important questions addressed by political psychologists interested in belief systems is how best to characterize individual differences in ideology. Though the nature of ideological variation is a topic of much debate (see Carmines & D'Amico, 2015; Duckitt & Sibley, 2010; Feldman & Johnston, 2014; Lewis, 2019), the most common assumption among researchers is that ideology varies on a unidimensional, left-right basis (Jost, 2006; see also Federico, 2020). Substantively, this schema is thought by many to contrast belief systems characterized by openness to social change and a preference for greater equality on the left and by preferences for stability and hierarchy on the right (Jost et al., 2009, 2013; Lipset, 1960). This characterization of ideology has its roots in the specifics of European history: indeed, the terms “left” and “right” refer back to the seating locations of radicals and conservatives in the French National Assembly in the late 18th century (Bobbio, 1996).

The left-right division plays a dominant role in the organization of political debate in many cultures (Benoit & Laver, 2006; Kitschelt et al., 2010; Knight, 1999; McCarty et al., 2006), and it has also been the focus of most behavioral and psychological research on the nature and foundations of ideological affinity (Federico, 2020). The left-right distinction is especially relevant to how governing elites and other opinion leaders organize and explain their preferences and decisions (Campbell et al., 1960; McCarty et al., 2006; Noel, 2014). Similarly, the most engaged segments of the mass public are more likely to rely on the left-right schema to organize their preferences and perceptions (Converse, 1964; Kalmoe, 2020; Kinder & Kalmoe, 2017). The practical importance of the left-right dimension is not surprising. A venerable line of formal analysis in political science has consistently noted that reliance on a single ideological dimension has the salutary property of simplifying political choices and making communication and understanding of politics more manageable in the face of coordination problems and human cognitive limitations (Downs, 1957; Hinich & Munger, 1994; Sniderman et al., 1991). By collapsing multiple dimensions of political conflict (spread across a potentially large number of issues) into a single axis of disagreement, left-right competition should be especially helpful to those most involved in the operational work of politics. In other words, it may be institutionally adaptive.

Though functional, the left-right distinction is contingent and fluid (Federico & Malka, 2018). Indeed, there is substantial debate about the relative importance of a durable substantive core versus alterable coalition-justifying elements to left-right ideology (Jost, 2006; Federico & Malka, 2018; Lewis, 2019; Morgan & Wisneski, 2017; Noel, 2014). Some work emphasizes the seemingly durable aspects of left-versus right ideology. In particular, the familiar divide between a preference for equality and an inclination to seek change (on the left) versus favoring hierarchy and the status quo (on the right) is arguably the most consistent symbolic axis of left-right competition—a pattern rooted in the fact that hierarchical social arrangements (whether aristocratic or capitalistic) have historically anchored the status quo in many societies (Bobbio, 1996; Federico, 2020; Jost, 2009; Jost et al., 2009; Lipset, 1960; McClosky & Zaller, 1984). In contrast, other symbolic and programmatic differences between the left and right show greater variance across societies and time periods, making it unwise to assume that the content of the left-right divide is a fact of nature (see Lewis, 2019; see also Federico & Malka, 2018). Policy positions, value emphases, and ideological rhetoric change over time as a function of elite coalition-building and new challenges (Noel, 2014).

For example, in debates over health care policy in the United States, support for an individual mandate to purchase health insurance shifted from being a “conservative” position to a “liberal” one, as conservatives adjusted their stance on the basis of challenges offered to the status quo by political actors on the left (Johnston et al., 2017). Similarly, center-right parties in advanced democracies have strategically shifted in their attitudes toward democracy, regulation of the free market, and other matters over time in order to best protect the interests of elite groups amid changing circumstances (Gidron & Ziblatt, 2019). Within the United States, the adjustment of “conservatism” to the rise of Donald Trump is an object lesson in the flexibility with which core ideological constructs are popularly defined (Hopkins & Noel, 2022; Lewis, 2019).

With both its durable and its malleable components, the left-right dimension has clearly been central to the way elite ideological differences have been structured in many places and times. However, its role in belief-system structure within mass publics is more complicated and contested (Converse, 1964; Kalmoe, 2020; Kinder, 2006; Kinder & Kalmoe, 2017; see also Federico & Malka, 2018). As studies of public opinion from a variety of advanced democracies over multiple decades suggest, many citizens (1) do not fully understand the conceptual distinction between left and right, (2) do not spontaneously use the left-right schema to describe political actors and events, and (3) do not hold ideologically-constrained positions across issues (Baldassari & Gelman, 2008; Converse, 1964; Kinder & Kalmoe, 2017). Moreover, as Philip Converse (1964) famously found, many citizens in the 1950s showed low levels of attitude stability on specific issues, suggesting that their opinions were effectively “non-attitudes” that lack a broader ideological anchor. Of course, the extent and kind of ideological structuring varies across contexts and time periods (Baldassari & Goldberg, 2014; Levendusky, 2009; Malka et al., 2019). Moreover, researchers have argued that mass publics may show greater evidence of stable, ideologically structured attitudes once random error in survey measures is statistically accounted for (Achen, 1975; Ansolabehere et al., 2008; Erikson, 1979; Hill & Kriesi, 2001; Judd & Milburn, 1980). Regardless, it is clear that left-right belief system structure in mass publics is found primarily among the stratum of citizens who are most knowledgeable of and interested in political affairs (Converse, 1964; Federico, 2021; Kalmoe, 2020; Sniderman et al., 1991; Zaller, 1992). Compared to their less-engaged compatriots, these individuals are more likely to have received and accepted elite ideological signals about “what goes with what” (Kinder & Kalmoe, 2017; see also Freeder et al., 2019; Groenendyk et al., 2020). Moreover, the traditional left-right system of belief organization is relatively uncommon globally, especially outside “WEIRD” (i.e., Western, educated, industrialized, rich, and democratic) nations (Malka et al., 2019; Marks et al., 2006; see also Federico, 2021). For example, using World Values Survey data collected in 90 nations, Malka and his colleagues find that the modal societal pattern is for conservative cultural preferences to be associated with left-leaning (rather than right-leaning market-oriented) economic preferences (Malka et al., 2019).

Taken together, these findings suggest that the left-right schema is an important basis for ideological variation, but also one whose reach is limited in significant ways (Morgan & Wisneski, 2017). In this respect, the division between left and right, while common, is not a fact of nature. It is not fixed—and neither are its relationships with other attitudes, identities, and psychological traits, a point we will return to below. The set of ideological packages available in a given society are social constructions. In large part, they reflect the discursive work of parties and their leaders, who assemble different issue positions and values into

the competing ideological frameworks that citizens choose from (Federico & Malka, 2018; Malka & Soto, 2015; Sniderman & Bullock, 2004); and intellectuals and pundits, who provide philosophical justifications for the ideological commitments that unify various political coalitions (Noel, 2014). As Converse (1964) noted long ago, ideologies most commonly derive their coherence from social cues provided by opinion leaders, rather than emerging solely on the basis of formal logic or bottom-up psychological motivations. This appears to be the case for the left-right schema as well, whose organization reflects the ways in which political elites have structured political competition in modern Western democracies (Federico & Malka, 2018; Jost, 2006).

2.3. Beyond the Left-Right Dimension: Multidimensional Conceptions of Ideology

Noting limits to the left-right dimension's explanatory reach, other perspectives on ideological variation suggest the existence of multiple dimensions of ideology (Federico, 2021; Feldman & Johnston, 2014; Malka et al., 2019). Though there are analyses that suggest higher numbers of ideological dimensions (Carmines et al., 2012; Layman & Carsey, 2002; Park, 2018), the most common multidimensional approach to ideology posits the existence of two ideological dimensions, which emerge in a bottom-up fashion in factor-analytic examinations of the structure of sociopolitical attitudes. The way these dimensions are defined and interpreted varies across disciplines. Within psychology, the first dimension has tended to broadly correspond with preferences for more versus less equality, whereas the second has corresponded with preferences for cultural openness and autonomy versus tradition, order, and uniformity (Duckitt, 2001; Federico, 2021; Schwartz, 1992). In a sense, this bidimensional model disaggregates the two facets of ideological difference that the unidimensional model joins together (i.e., orientations toward equality and openness to change versus hierarchy and tradition; Jost, 2009) and argues that they vary in the extent to which they consistently overlap (Federico & Malka, 2018). Evidence for this bidimensional structure can be found across a variety of domains, most notably in the organization of value preferences and worldviews (e.g., Braithwaite, 1997; Duckitt, 2001; Schwartz, 1992; Stangor & Leary, 2006).

Within political science, these dimensions often deal with variation in the types of policy preferences queried in public opinion surveys. In particular, factor analyses of such survey data find that economic preferences (i.e., over government intervention in the economy and support for social welfare) and sociocultural preferences (i.e., over religion, multiculturalism, and traditional values) reliably fall on different factors (e.g., Carmines et al., 2012; Evans et al., 1996; Feldman & Johnston, 2014; Fleishman, 1988; Knoke, 1979; Shafer & Claggett, 1995; Treier & Hillygus, 2009). Consistent with the idea that these two-dimensional models are, to a degree, parallel, research suggests that attitudes toward economic issues relate more strongly to the egalitarianism value dimension, while attitudes toward sociocultural issues relate more strongly to the openness versus tradition value dimension (Duckitt & Sibley, 2010; see also Federico, 2021, Johnston et al., 2017, for reviews).¹

Duckitt and colleagues' dual-process model of ideology and prejudice (Duckitt, 2001; Duckitt & Sibley, 2010) provides perhaps the most systematic account of how and why

attitudes and beliefs can be characterized using two dimensions. The dual-process model argues that the equality-inequality and openness-tradition dimensions can be captured respectively by *social dominance orientation* (SDO, a general preference for group-based hierarchy; Sidanius & Pratto, 1999) and *right-wing authoritarianism* (RWA, an inclination toward deference to ingroup authorities, conventionalism, and hostility toward outsiders and norm-violators; Altemeyer, 1998). In turn, the model suggests that these two “ideological attitude systems” are rooted in distinct worldviews and traits. Whereas the SDO/equality dimension rests on a view of the world as competitive and ruthless and on toughminded personality traits, the RWA/tradition dimension rests on a view of the world as dangerous and conformity-related traits (Duckitt, 2001). Put another way, the dual-process approach suggests that the SDO dimension reflects competitive, dominance-oriented motives, and that the RWA dimension reflects needs for security, safety, and certainty.

Though distinct, these two dimensions do overlap somewhat—albeit to a varying extent across political environments and individuals (Federico, 2020, 2021; Petersen, 2015; Weeden & Kurzban, 2014). In some cases, the two dimensions are constrained in the usual “left-right” way, such that preferences for equality are aligned with cultural openness and preferences for hierarchy are aligned with support for tradition and the status quo. In other cases, they are not. As Federico and Malka (2018) note, the packaging of the two dimensions depends in large part on a polity’s history and on how its elites tie together concerns from different political domains. The standard, “matched” left-right alignment of the two dimensions prevails in nations that are more economically developed, secularized, and culturally liberal, and in nations that were not part of the former communist bloc (Malka et al., 2014, 2019). In these countries, elites have tended to pair egalitarian economic positions with more culturally liberal social positions. However, outside of this set of nations, it is actually more common for egalitarianism and left-wing economic views to be slightly positively correlated with traditionalism and conservative cultural views (or vice versa)—a pattern Malka, Lelkes, and Soto (2019) refer to as the “protection versus freedom” belief-system organization.

However, even within nations where egalitarianism is aligned with cultural openness and left-wing (versus right-wing) economic positions are aligned with left-wing (versus right-wing) cultural positions, left-right consistency is not found to the same extent among all citizens. Though left-right packaging predominates among political elites and activists in these countries (Converse, 1964; Jennings, 1992), only those segments of the mass public that are attentive to signals from political elites about what goes with what show clear left-right alignment across dimensions and issue domains (Federico, 2021; Feldman & Johnston, 2014; Layman & Carsey, 2002; Malka et al., 2019). In sum, social and historical context—and elite opinion leadership in particular—play a key role in determining how the two core dimensions of ideological variation align with one another.

2.4. The Dispositional Bases of Ideology

Besides examining the nature of ideological differences, political psychologists have also taken a perennial interest in the dispositional bases of ideological affinity—that is, the psychological motives and characteristics that predict ideological orientations (Jost et al., 2003, 2009, 2013; see also Federico & Malka, 2018). Though the precursors of this approach go

back as far as classical sociology in the modern era (e.g., Weber, 1948; see also Gerth & Mills, 1953; Lasswell, 1948), the key impetus for work in this area goes back to post-war efforts to identify the antecedents of support for fascist ideology—most notably, early work on the authoritarian personality (e.g., Adorno, Frenkel-Brunswick; Levinson & Sanford, 1950; see also Allport, 1954). Subsequently, this approach was extended in order to make sense of the dispositional antecedents of extremism in general (Eysenck, 1954; Lipset, 1960; Rokeach, 1960) and “normal” left-right variation of the non-totalitarian sort (McClosky, 1958; Tomkins, 1963; Wilson, 1973).

Though work on the dispositional roots of ideology went out of style for some time, it was revived shortly after the turn of the century due in no small part to the work of social psychologist John Jost and his colleagues (Jost, 2009; Jost et al., 2003, 2009). The main conclusion that has been drawn from this contemporary body of work is that variables reflecting high (versus low) levels of psychological rigidity and threat sensitivity predict right-wing (versus left-wing) ideological preferences (Federico, 2021; Jost et al., 2009). This conclusion is sometimes characterized as the “rigidity of the right” perspective (Federico, 2021; Malka et al., 2017). An exhaustive review of the relevant literature would require a chapter in and of itself, so we refer the reader to canonical reviews of research on this topic (e.g., Federico & Malka, 2018; Jost et al., 2003, 2009, 2013; Jost, 2017) and provide only a brief summary of evidence and ongoing debates here.

First of all, one of the most examined dispositional predictors of political ideology is *authoritarianism* or the *authoritarian predisposition*, which reflects individual differences in deference to group authority and ingroup norms (Adorno et al., 1950; Altemeyer, 1998; Duckitt, 2001; Duckitt & Bizumic, 2013; Stenner, 2005). Individuals high in authoritarianism have stronger needs for security and are more sensitive to threat (Duckitt & Sibley, 2010; Feldman, 2003; Hetherington & Weiler, 2009; Lavine et al., 1999; Lavine et al., 2002). As such, those high (versus low) in authoritarianism tend to prefer conservative (versus liberal) positions on cultural matters and tend to identify as politically conservative, perhaps to avoid the risks associated with deviation from the status quo (Federico et al., 2011; Federico et al., 2009; Feldman, 2003; Hetherington & Weiler, 2009; Jost et al., 2009). Feldman and Weber (Chapter 20, this volume) review this literature.

Another variable commonly linked to ideological differences is the *need for cognitive closure* (Kruglanski, 2004; Kruglanski & Webster, 1996; Kruglanski et al., 2006), a tendency to avoid uncertainty by “seizing” more on available information as quickly as possible to draw conclusions and by “freezing” on those conclusions even in the face of a changed information environment. Research consistently suggests that individuals high (versus low) in need for closure are more likely to hold conservative political identities and cultural issue preferences (Federico et al., 2012; Federico & Goren, 2009; Jost et al., 2003, 2009; Kimmelmeier, 1997; Van Hiel et al., 2004; Van Hiel et al., 2010; see also Ruisch & Stern, 2021). Related findings suggest links between cognitive flexibility and analytic and exploratory thinking styles, on one hand, and liberal political identity and (mostly cultural) stances, on the other (e.g., Jost et al., 2017a; Pennycook et al., 2019; Zmigrod et al., 2021; see also Ruisch et al., 2020; Shook & Fazio, 2009).

Similar patterns arise in studies of personality, values, and morality. With respect to personality, studies using the five-factor model of personality (McCrae, 1996) consistently find that individuals high in openness to experience are more likely to hold liberal identifications and liberal preferences on many issues, whereas those high in conscientiousness are more

likely to hold conservative identifications and issue preferences (e.g., Bakker, Chapter 2, this volume; Carney et al., 2008; Gerber et al., 2010, 2011; McCrae, 1996; Mondak, 2010; for analogous results using measures of open-minded thinking, see Pennycook et al., 2020). Given the conceptual content of these traits, these patterns are consistent with the assumptions of the rigidity-of-the-right model: openness implies stronger tolerance of uncertainty and risk, whereas conscientiousness implies an emphasis on duty and restraint (McCrae & Costa, 2003).

With respect to values, work using Schwartz's (1992) model of human values finds that a preference for security-providing *conservation values* (i.e., tradition, conformity, and security) over exploration-oriented *openness values* is reliably associated with right-wing (versus) left-wing political identifications and cultural preferences (i.e., stimulation and self-direction; Caprara et al., 2006; Goren, 2012; Malka et al., 2014; Schwartz, 1992, 2007; Thorisdottir et al., 2007). Finally, with respect to morality, research relying on moral foundations theory finds that individuals who place greater importance on *binding* moral concerns linked to group loyalty, deference to authority, and moral purity—concerns linked to shoring up communal social ties in the face of insecurity and danger—are more likely to hold conservative political identities and cultural attitudes (Graham et al., 2009; Haidt, 2012; Koleva et al., 2012; see also Federico et al., 2013; Weber & Federico, 2013).

Large-scale meta-analytic studies conducted in recent years provide evidence consistent with these basic patterns, with some caveats that we will return to below. For example, Jost, Stern, Rule, and Sterling (2017b) examined data from 134 studies and found “small-to-moderate” relationships between variables linked to the salience of fear and threat and support for several right-wing policies, parties, and leaders. Similarly, Jost, Sterling, and Stern (2017a) aggregated results from 181 samples including 133,796 participants and observed significant relationships (1) between measures of needs for structure and order, need for closure, intolerance of ambiguity, rigidity, and dogmatism and several right-wing preferences, and (2) between measures of integrative complexity, analytic thinking, need for cognition, and uncertainty tolerance and several liberal preferences.

Recent research using methods other than meta-analysis finds roughly similar patterns. For instance, Zmigrod and her colleagues (2021) used a data-driven approach based on Bayesian and drift-diffusion modeling techniques to map relationships between cognitive and personality dimensions and ideology.² In addition to finding that cognitive and personality variables consistently had stronger relationships with ideology than demographics did, they also found that conservative attitudes were associated with greater caution in perceptual decision-making and that cultural conservatism was linked with information-processing styles that were less flexible, complex, and reliant on working memory and with lower levels of risk-taking and greater risk perception.

When evaluating evidence for the rigidity-of-the-right model, there are nevertheless some recurring methodological and interpretative issues whose implications must be considered. Malka, Lelkes, and Holzer (2017) documented three of these: content overlap between psychological and political measures, insufficient attention to differences in the psychological correlates of cultural and economic political attitudes, and lack of attention to the role of political information environment in conditioning links between psychological variables and political attitudes. Occurrences of these issues are too numerous to document comprehensively here (see Malka et al., 2017), but it will suffice to provide a few examples. Research on the salience of fear and threat frequently uses measures of these constructs

that are overtly politicized, such as threat of terrorism and loss of white majority status (Jost et al., 2017b). When attention is paid to the specifically politicized nature of different threats, results do not show a directionally consistent relationship between threats and political orientation (see Brandt et al., 2021; Crawford, 2017; Hatemi & McDermott, 2020). In addition, the rigidity-of-the-right model often fails to account for why psychological variables that supposedly predict a broad-based conservative orientation often fail to predict right-wing positions in the economic domain, which is recognized by political scientists as central to left-right-differences in most advanced democracies (see Duckitt & Sibley, 2010; Johnston et al., 2017; Malka et al., 2014). Finally, the strength and even direction of relationships between psychological attributes and political attitudes vary considerably across factors that serve as proxies for exposure to different political information environments (Federico & Malka, 2018). Below we discuss research on moderators of disposition-politics links that is attuned to these issues.

2.5. Moderators of the Relationship Between Dispositions and Ideological Preferences

Though the relationship between high (versus low) psychological rigidity and threat sensitivity and many right-leaning (versus left-leaning) preferences is well established at this point, evidence also increasingly suggests that these relationships are moderated by a number of individual and contextual factors, in predictable and theoretically coherent ways. Like the literature on dispositional variables and ideology itself, this body of work is extensive (see Federico, 2021; and Federico & Malka, 2018, for more exhaustive reviews). Below, we cover the key types of moderators that have been examined.

Issue domain. Perhaps the most important moderator is the type of political issue measured in a given analysis. As noted previously, political preferences are usefully described in terms of a two-dimensional structure corresponding in the policy realm to economic issues and sociocultural issues (Duckitt & Sibley, 2010; Feldman & Johnston, 2014). In general, variables indicative of psychological rigidity and threat sensitivity more strongly predict ideological conservatism in the sociocultural domain than the economic domain; relationships between these dispositions and economic preferences are weak and inconsistently signed (Federico et al., 2014; Federico & Malka, 2018; Johnston et al., 2017; Malka & Soto, 2015; see also Costello & Lilienfeld, 2020). This pattern is found for authoritarianism (Cizmar et al. 2014; Feldman & Johnston, 2014), need for closure (Chirumbolo et al., 2004; et al.; Kossowska & Van Hiel, 2003; Van Hiel et al., 2004; Yilmaz & Saribay, 2016), and endorsement of conservation versus openness values (Duckitt, 2001; Duriez et al., 2005; Malka et al., 2014). It also shows up for Conscientiousness and Openness from the Big Five, though less consistently (Carney et al., 2008; Mondak, 2010; but see Clifford et al., 2015).³

The asymmetry likely reflects the “harder” nature of economic issues, which are not as easy to symbolically connect with dispositional preferences for security, certainty, and structure as issues like abortion, LGBT rights, and immigration (Carmines & Stimson, 1980; Johnston et al., 2017; Johnston & Wronski, 2015; Malka & Soto, 2015). It may also reflect the unique dynamics of opinion formation in the economic sphere, where indices of psychological rigidity and threat sensitivity relate to right-wing economic preferences in

opposite directions among those low and high in political engagement (leading the effects to cancel out at the full-sample level; Federico & Malka, 2018). Finally, other research suggests motives other than those related to needs for security and certainty may matter in the economic domain. For example, Duckitt's (2001) dual-process model of ideology suggests that traits associated with competitiveness, ruthlessness, and tough-mindedness predict right-wing economic preferences (see also Bakker, 2017; Bardeen & Michel, 2019; Duckitt & Sibley, 2010; Gerber et al., 2010; Kettle & Salerno, 2017).

Exposure to elite discourse. Factors governing citizen exposure to elite political discussion also moderate the relationship between psychological variables and ideological preferences. As we have argued, ideologies are socially constructed, and different packages of political positions acquire their symbolic meaning largely through the creative work of political elites operating within the constraints imposed by the history and conditions of a particular society (Noel, 2014; Sniderman & Bullock, 2004; Federico & Malka, 2018). Consistent with the idea that society-level discursive and historical factors condition the relationship between dispositions and ideological affinity, research suggests that variables like a preference for conservation over openness values (Malka et al., 2014, 2019; Piurko et al., 2011; Schwartz et al., 2014; Thorisdottir et al. 2007), need for closure (Kossowska & Van Hiel, 2003), and low Openness to Experience (Roets et al., 2014) are either unrelated to ideology or associated with stronger preferences for the left in former communist nations, where the left is associated with authoritarianism and perceived as representing an orderly past. Moreover, dispositional needs for security and certainty are more strongly related to ideological conservatism in nations at higher levels of development, where social liberalization has occurred and sociocultural divides over traditional values have emerged and become part of the broader left-right divide (Federico & Malka, 2018; Malka et al., 2014, 2019; see also Benoit & Laver, 2006; Lefkoridi et al., 2014). As noted above, indices of rigidity and threat sensitivity are more strongly related to social attitudes than economic ones, so the grafting of a sociocultural divide onto pre-existing left-right disagreement over economics makes it easier for citizens to sort into different ideological preferences (Johnston et al., 2017; Malka & Soto, 2015) and partisan identities and voting patterns (Cizmar et al., 2014; Hetherington & Weiler, 2009) as a function of their basic psychological dispositions.

At the individual level, political engagement also consistently moderates the relationship between psychological dispositions and ideological preferences. All other things being equal, individuals high in political engagement are more likely to attend to elite signals about what different ideological labels mean and what goes with what ideologically (Converse, 1964; Kalmoe, 2020; Kinder & Kalmoe, 2017). In addition to having a better understanding of what different ideologies mean, those high in political engagement are also more concerned about using their issue stances to signal their broader political allegiances (Kahan, 2015a). As a result, they should find it easier to sort into the ideological identities and positions that best match their psychological motives and characteristics (Federico, 2021; Federico & Malka, 2018). Consistent with this expectation, variables like authoritarianism (Federico et al., 2009, 2011; Johnston et al., 2017), need for closure (Federico & Goren, 2009; Johnston et al., 2017; see also Federico & Ekstrom, 2018), low Openness to Experience and high Conscientiousness (Johnston et al., 2017; Osborne & Sibley, 2012, 2015), and a preference for conservation over openness values (Johnston et al., 2017; Malka et al., 2014, 2019) are all more strongly correlated with ideological conservatism among the highly engaged. Similar patterns are found for the relationship between variables like

authoritarianism and need for closure and political identifications that are linked to ideology, such as Republican partisanship in the United States (Federico & Reifen-Tagar, 2014; Johnston et al., 2017).

Interestingly, engagement *reverses* the relationship between needs for security and certainty and the left-right tilt of one's preferences in the economic realm (as noted briefly above). Among those high in engagement, individuals who prefer certainty, security, and structure tend to adopt more right-wing economic attitudes, favoring the free market and less redistribution. Among those low in engagement, the pattern reverses: individuals who prefer certainty, security, and structure tend to adopt more left-wing positions, favoring greater government intervention and redistribution (Johnston et al., 2017; Malka et al., 2014). This pattern has been found for authoritarianism, need for closure, dispositional risk aversion, conservation versus openness values, and the Openness and Conscientiousness dimensions of the Big Five (Federico & Malka, 2018; Malka & Soto, 2015).

This reversal reflects different processes of economic-preference formation among those low and high in engagement (Johnston et al., 2017). Among those low in engagement, there is a direct instrumental impact of dispositions, such that those with more rigid, threat-sensitive dispositions favor left-wing economic policies as a form of insurance against the risks and dangers of a market economy. Among those high in engagement, the impact of "rigid" preferences for certainty, security, and structure are indirect and more heavily shaped by the abstract ideological meanings that political elites attach to market-oriented versus redistributionist economic positions. Individuals who are more attentive to politics are more likely to gravitate toward the ideological and partisan identities that best match their dispositions and adopt the economic positions that go along with those identities. Thus, engaged citizens who are more psychologically rigid or sensitive to threat sort themselves into right-wing ideological and partisan identities due to a symbolic preference for established ways of doing things and adopt the market-oriented economic positions associated with those identities. In contrast, engaged citizens who are more psychologically flexible and less threat-sensitive sort themselves into left-wing ideological and partisan identities due to their greater openness to change and adopt the interventionist positions implied by those identities.

Thus, the reversal found among those high in engagement reflects the meanings that have been typically assigned to different economic doctrines by political elites in many societies, in which support for the free market is seen as shoring up the status quo and support for redistribution and regulation of business is seen as progressive social change (Federico & Malka, 2018). Consistent with the argument that the symbolic meaning of economic positions in various social contexts is crucial to this process, the reversal effect dissipates in the nations of the former communist bloc (where left-wing positions represent an older, more traditional way of doing things; Malka et al., 2014), in nations where left-wing economic positions are not consistently tied to socially liberal positions that individuals high in needs for security and certainty are especially averse to (Malka et al., 2019), and in nations where high levels of redistributive and social welfare spending are seen as morally normative by much of the population (e.g., Nordic and eastern European nations; Czarnek & Kossowska, 2019).

Race and ethnicity. Several studies suggest that the typical relationship between dispositional preferences for certainty, security, and structure breaks down among members of racial and ethnic groups that have historically been subject to subordination

and oppression. Among members of these groups, the usual tendency for those who score higher on indices of rigidity and threat sensitivity to favor the status quo and adopt conservative positions comes into conflict with a motivation to protect the ingroup's interests (Federico et al., 2021). If one belongs to a racial or ethnic group that is disadvantaged by the status quo, political conservatism may not be as security- and certainty-enhancing as it is for members of groups that enjoy a dominant position under existing arrangements (though some members of subordinate groups resolve this conflict in favor of system support; see Jost, 2020). Consistent with this expectation, research in the United States finds that authoritarianism (e.g., Dusso, 2017; MacWilliams, 2016), low Openness and high Conscientiousness (Gerber et al., 2011), and numerous other variables indicative of high needs for security and certainty more weakly relate to conservative identities and preferences among Black Americans and Latinos (Johnston et al., 2017). Pérez and Vicuña (Chapter 25, this volume) discuss the political psychology of minority status.

Type of dispositional measure. Though research suggests that psychological motives and characteristics relate to ideological preferences, this relationship is generally stronger when psychological dispositions are measured using self-reports rather than behavioral measures of psychological functioning. For example, several meta-analyses indicate that self-report personality measures of needs for certainty, security, and structure correlate more strongly with cultural conservatism than behavioral measures of how inflexibly or aversively individuals respond to complex, changing, or threatening stimuli (Van Hiel et al., 2016; Van Hiel et al., 2010). Similarly, while earlier studies suggested that behavioral and physiological measures of threat sensitivity were associated with social conservatism, subsequent studies using larger sample sizes have failed to replicate this result (Bakker et al., 2020; Fournier et al., 2020; Osmundsen et al., 2021; Smith & Warren, 2020). This asymmetry could reflect the limitations of self-reports as objective measures of how well individuals manage uncertainty, threat, and complex cognitive operations (Bakker et al., 2020). For example, self-report measures related to needs for security and certainty do not correlate with behavioral displays of politically biased reasoning (Guay & Johnston, 2022) and might be biased, themselves, by political orientation (Bakker et al., 2020; Ludeke et al., 2016). In some instances, self-report measures of this sort contain overtly political content, which exaggerates their correlation with ideology (Conway et al., 2016; Malka et al., 2017). However, the asymmetry may also be due to the lower reliability of behavioral measures (Dang et al., 2020) or the stronger match between the task demands of explicit political attitude measures and self-reports of personality compared to behavioral measures that do not require introspective, conscious judgments (Federico, 2021).

2.6. Is the Right Always More “Rigid”?

As noted previously, research on the relationship between psychological variables and political ideology is often interpreted as supporting a rigidity-of-the-right model (Malka et al., 2017). With respect to the relationship between cultural conservatism and many *dispositional measures* of rigidity and threat sensitivity, this pattern seems to be well supported (see Jost, 2009, 2017). At the same time, other research suggests that *situational manifestations* of rigidity may be more symmetric in their distribution across the ideological spectrum (Harper, 2020; see also Conway et al., 2018; Costello et al., 2021). Specifically,

despite well-established ideological asymmetries in dispositions, individuals on both the right and the left may become defensive, rigid, and intolerant when the validity of established political identities or attitudes are threatened or challenged.

This tendency manifests itself in several ways. For example, individuals on both the right and left exhibit motivated reasoning in defense of their worldviews when challenged (Ditto et al., 2019; Guay & Johnston, 2022; see also Cohen, 2003; Washburn & Skitka, 2017)—a pattern that often becomes stronger as political knowledge increases (Kahan, 2015b). Similarly, individuals at both ends of the left-right dimension avoid perspectives that diverge from their own (Collins et al., 2017; Frimer et al., 2017), though some evidence suggests that this tendency is somewhat stronger on the right (Nam et al., 2013; Rodriguez et al., 2017). Recent efforts to develop self-report measures of authoritarianism on the left also find subsets of individuals on both the left and right poles of the ideological spectrum that exhibit moral absolutism and intolerance of political opponents (Conway et al., 2018; Costello et al., 2021).⁴ Finally, as noted above, relations between feelings of fear and threat and ideology vary considerably depending on the types of threats assessed (Brandt et al., 2021; Hatemi & McDermott, 2021; Malka et al., 2017).

Evidence of symmetry is also found with respect to cognitive manifestations of rigidity. Compared to centrists, those with extreme views are more likely to overestimate how much knowledge they possess (van Prooijen & Krouwel, 2019). They also prefer to solve problems in relatively simple ways and experience a greater sense of certainty about the solutions they reach (van Prooijen et al., 2018). Individuals whose views are further away from the political center are also more likely to cognitively represent politics in a less complex fashion (Lammers et al., 2017; Tetlock, 1984), though other lines of research suggest that it is centrists who show lower levels of political knowledge and complexity in their representations of the political world (e.g., Sidanius, 1988; Treier & Hillygus, 2009). Finally, individuals on the left and right may be more rigid or flexible in different contexts. For example, though initial evidence suggested that those identified with the right are more cautious and focused on avoiding negative outcomes in exploration tasks (Shook & Fazio, 2009), this may reverse in contexts that those on the political right are more positively oriented toward (e.g., stock markets; Fiagbenu et al., 2019; Ruisch et al. 2020).

Though these results may appear to be at odds with work on left-right differences in dispositional rigidity, symmetry in situational rigidity makes sense in terms of theory and research on the consequences of commitments that are central to a person's identity (Federico, 2021). Politics is largely about important social identities (such as symbolic ideology and partisanship), and human beings are motivated to defend the worth of their identities—regardless of whether that identity has left-wing or right-wing content (Huddy, 2001; Tajfel & Turner, 1986; see also Campbell et al., 1960; Green et al., 2002; Kahan, 2015a; Mason, 2018; Van Bavel & Pereira, 2018). Other political preferences beyond broad identities like ideology and partisanship (e.g., attitudes toward specific political issues) can also become central to the self, and when they do they will also be defended “rigidly” in the face of attack (Krosnick, 1988; Kunda, 1990; Lodge & Taber, 2013).⁵

Thus, dispositional and situational forms of rigidity may relate to ideological variation in different ways. In this context, it is important to avoid the “jingle-jangle” fallacies, in which constructs with similar names are erroneously assumed to be the same and constructs with different names are incorrectly assumed to be distinct (Block, 1995). Though the dispositional and situational measures we review implicate some form of “rigidity,” they

reflect different processes with respect to ideological preferences. On one hand, variables related to dispositional rigidity (or unobserved antecedents of those variables; Hatemi & Verhulst, 2015) may govern sorting into different ideological camps, with those higher (versus lower) in dispositional rigidity sorting into the right (versus the left). On the other hand, variables related to situational rigidity may reflect efforts to defend political commitments that are important to a person's identity, regardless of what end of the left-right spectrum they are on (Brandt & Crawford, 2020; Federico, 2021).⁶ A critical goal for future work is to explore the exact interplay between these dispositional and situational processes, with an eye to determining whether observed left-right differences in defensiveness and rigidity are directly attributable to underlying dispositional differences or reflect other processes (Eichmeier & Stenhouse, 2019).

2.7. Is Ideology Genetically Transmissible?

Finally, a substantial volume of research has now addressed the possibility that political preferences—like the personality traits that have been found to predict those preferences—have a heritable, genetic component (for a more detailed review, see Ksiazkiewicz & Friesen, 2017; Settle & Detert, Chapter 8, in this volume). As we will discuss below when we turn to the social bases of belief-system structure, research in political science has traditionally assumed that ideological orientations are transmitted from one generation to the next via socialization within the family and other social relationships and groups (e.g., Sears & Brown, 2013). Research on the biological heritability of political preferences challenges this assumption.

Most of this research uses the classic twin design developed by behavioral geneticists, which compares the attitudes of monozygotic twins (who are genetically identical) and dizygotic twins (who share approximately 50% of their genetic makeup). Given the assumption that twins within both kinds of pairs receive similar environmental influences, this design can be used to obtain estimates of trait variance due to genes and environment (Alford et al., 2005; Hibbing et al., 2014). Studies using this method suggest 40% to 50% of the left-right variance in individuals' attitudes can be attributed to additive genetic influences (see Gonzales et al., in press). Importantly, estimates of attitude heritability pertain to populations, not individuals, and heritability may thus vary across populations subject to different influences (Ksiazkiewicz & Friesen, 2017). Consistent with this principle, the proportion of variance attributable to genetic effects is larger among those high in political engagement, in recent behavior-genetic studies (Kalmoe & Johnson, 2022). This suggests that genetic influences on ideological affinity are most likely to actually impact preferences in populations that better understand politics (and the ideological meaning of different political preferences) due to their greater exposure to elite political discourse and other aspects of the political information environment in a particular society.

Though this approach has generated much-needed attention to the possibility that political preferences may be subject to biological as well social influences, aspects of the twin methodology have been criticized, including its assumptions that monozygotic and dizygotic twins experience comparable environments and that genes do not interact with each other or lead individuals to sort into environments with different influences on attitudes (Charney, 2008; Shultziner, 2013). Given that many of the dispositional correlates

of ideology reviewed above also appear to be heritable, it is quite possible that observed relationships between personality and ideology may be due to common genetic influences (a pattern referred to as “pleiotropy” in the genetic literature) rather than a direct causal effect of personality on ideology (Hatemi & Verhulst, 2015; Osborne & Sibley, 2020; for a review, see Ksiazkiewicz & Friesen, 2017). Further research will be needed to clarify this issue.

3. A CLOSER LOOK AT THE SOCIAL NATURE OF IDEOLOGY

As our review above suggests, ideological belief systems emerge from the interplay of (1) underlying psychological needs and (2) features of an individual’s social and political context. The contextual features that would appear to be most important in this regard are those that provide information about how attitudes and beliefs should be packaged together—information that ultimately emanates from elite messages (Converse, 1964; Zaller, 1992). In many cases, people receive this information and use it when forming or adjusting their political attitudes and beliefs.

This section addresses *why* they do so; in other words, the nature of the psychological processes that energize and direct people toward adoption of attitudes and beliefs that are deemed congruent with their ideological commitments. Belief system congruence has often been framed in terms of purely intrapsychic processes having to do with needs for dissonance reduction and cognitive consistency (Heider, 1958; Shafer, 1981). But a key point we wish to make is that the psychological processes underlying ideological coherence are inherently *social* (Coppock & Green, 2022; Jost et al., 2008; Rossignac-Milon & Higgins, 2018; Kahan, 2015a; Kruglanski et al., 2006). Below, we review theory and evidence for relationships with close others, social identifications with salient political groups, and rational deference to trusted elites as sources of belief-system structure.

3.1. Relationships with Close Others as a Source of Belief-System Structure

One important way that the psychological processes underlying belief system coherence are inherently social has to do with motives for bonding, intimacy, and approval from close others. For example, classic research on the inter-generational transmission of political attitudes demonstrated that ideological positions are likely to be transmitted from parents to children, especially to the extent that both parents have similar political beliefs and the family discusses politics frequently (Jennings & Niemi, 1968).⁷ Meanwhile, there are long-established research traditions addressing the importance of political communication networks and deliberation for political attitudes and beliefs (Berelson et al., 1954; Huckfeldt et al., 2004; Mutz, 2006). A review of these literatures is beyond the scope of this chapter, but here we summarize some key insights about the roles of motives for interpersonal bonding and closeness in holding together ideological belief systems.

Evidence suggests that desire for closeness with important others can motivate people to align their own social and political opinions more closely with the perceived views of those other individuals (Jost et al., 2008; Stern & Ondish, 2018). According to shared reality theory (Hardin & Higgins, 1996), this is done to maintain and solidify important social relationships by establishing a sense of shared reality. Indeed, the long-acknowledged role of consistency motivation in belief system structure seems to have a lot more to do with interpersonal processes than early formulations suggested (Rossignac-Milon & Higgins, 2018). Specifically, the intensity of dissonance-reduction motives seems to depend on whether or not a shared reality with liked others is at stake (e.g., Cooper and Fazio, 1984; Cooper et al., 1974; Echterhoff et al., 2005). Indeed, the enforcement of conformity in views is central to intra-group processes in general, and the construction of realities (including the beliefs representing political reality) are likely “conducted interactively with fellow members of groups to which we belong and that we deem important” (Kruglanski et al., 2006, p. 84).

In fact, if one fully acknowledges the importance of primary social relationships to human flourishing, the potential rationality of seemingly irrational political positions comes into focus. Kahan (2015a) notes that for many people there is “expressive rationality” in the adoption of ideologically congruent views that are inaccurate or seemingly contrary to the individual’s material self-interest. If the political positions associated with one ideological posture seem to favor policies that would realistically improve one’s material situation but the positions of the opposing ideological posture are fervently held by one’s close friends and family, which positions is it rational for the individual to adopt? Given that the individual’s political behavior will have no detectable impact on policy outcomes (e.g., Downs, 1957 but might well have consequences for their relationships with close others, it could be “rational” to adopt the latter.

When considering how motives to be close to others can facilitate ideological cohesion, social media may play an important role in contemporary contexts. Specifically, much political discussion takes place on social media, and some evidence suggests that this may go hand-in-hand with ideological polarization (Lee, 2016; Lee et al., 2014; though see Boxell et al., 2017). Bond and Messing (2015) found that people were more likely to be in ideological agreement with those Facebook friends with whom they share close social ties. Barbera et al. (2015) found that Twitter users generally interact with ideologically similar others, and this is especially true of users on the political right. Findings such as these are likely to in part reflect selection of close others and frequent interaction partners on the basis of political homophily. But the desire to reinforce social bonds may lead individuals to develop or amplify ideological agreement with close others on social media (Tufekci, 2018). And even if people interact with politically dissimilar others on social media, there is reason to expect that this would not lead to moderation of political attitudes and could sometimes yield a “backfire effect” resulting in more extreme attitudes (Bail et al., 2018).

The rising polarization in societies such as the United States may also increase the power of bonding and intimacy motives to promote ideological coherence among citizens. As the United States has become affectively polarized, Americans’ marriage and dating preferences may be increasingly based on political homophily (Alford et al., 2011; Huber & Malhotra, 2017; Iyengar et al., 2018). There is also some evidence that Americans find those with opposed ideological and partisan views less attractive (Mallinas et al., 2018; Nicholson et al., 2016) or at least that they are motivated to claim that they do (Yair & Huber, 2020). Even when individuals do not select partners on the basis of ideological similarity per se, they

may do so on the basis of other characteristics that are correlated with politics, leading to more highly correlated ideological views between partners (Klofstad et al., 2013). Thus, if fewer Americans are romantically involved with ideologically dissimilar others, there is less opportunity for bonding motives to propel departures from ideologically constrained belief systems.

The likelihood of close others reinforcing existing political predispositions also increases to the extent that Americans have sorted into politically congenial areas. How much Americans are geographically segregating on the basis of political preferences is currently a matter of debate, though (Bishop & Cushing, 2008; Mummolo & Nall, 2017). Recently, Martin, and Webster (2020) reported evidence that Americans are sorting based on non-political lifestyle factors (e.g., population density) that happen to correlate with political preferences, but only to a small extent. In fact, as the authors note, one would expect *far less* geographical polarization than what is present in the United States, given the frequency with which Americans move and the modest extent to which politics and related lifestyle preferences influence their moving decisions. Martin and Webster (2020) contend that the most likely explanation for this is that citizens come to adopt the political preferences that are represented in their area, consistent with the general view that geography has a strong influence on political cognition (Enos, 2017).

Even for Americans who do have politically diverse social networks, there are forces that work against any tendency these networks might have to promote ideologically cross-cutting belief systems. For example, motives for harmonious interpersonal interaction often inhibit people from expressing political disagreement (Gerber et al., 2012; Noelle-Neumann, 1974), which can have the consequence of enhancing the homogeneity of political discussion networks (Cowan & Baldassari, 2018). In this regard, Mutz (2006) noted an intrinsic tension between promoting a politically active citizenry and one that is interpersonally exposed to attitude-challenging communication. To the extent that people have politically diverse discussion networks, she found, they were *less* likely to engage actively with politics; rather, politically homogenous discussion networks nurtured more political activism.

3.2. Social Identification with Political Groups as a Source of Belief-System Structure

Social identity refers to emotionally important self-categorization as a member of a social group (Tajfel & Turner, 1986). It is probably the most frequently invoked concept for integrating societal and individual psychological levels of analysis in the social sciences (Brewer, 2001; Hogg et al., 1995). Because the study of ideological belief systems inherently involves such integration, the importance of social identity for such belief systems is often recognized, either directly or indirectly (Haas et al., 2019; Huddy & Bankert, 2017; Layman & Carsey, 2002; Malka & Lelkes, 2010).

The prior section addressed the roles of interpersonal bonds in holding ideological belief systems together, and in many cases these bonds are held with others with whom one shares a larger group-based identity. But there is an important distinction between groups that are mainly based on interpersonal bonds and those that are mainly based on a common social identification (Prentice, Miller & Lightdale, 1994). The nature of the larger groups

people socially identify with vary a great deal, and they include ethnic groups, social classes, genders, nationalities, and religions. Many are explicitly political, including ideological groups (e.g., conservatives), groups defined by position on a salient issue (e.g., Remainers in the context of the Brexit debate in the UK), social movements (e.g., Black Lives Matter), and, perhaps most prominently, political parties. These types of social identities structure political thinking and motivate people to form and represent themselves as possessing attitudes and beliefs that are consistent with the social identity (Federico & Malka, 2018; Johnston et al., 2017; Kahan, 2015a).

A comprehensive account of how social identity (in all its various forms) relates to ideology is beyond the scope of this chapter. Instead, we narrow our focus in two ways. First, we zero in specifically on the role of social identity in holding different political idea-elements together. Second, because many forms of social identity (see Brewer, 2001; Deaux, 1996; Thoits & Virshup, 1997) are likely to exert their influence on political attitudes via their incorporation into *explicitly political* social identities, we focus only on the latter (also see Mason, Chapter 24, this volume). In short, we focus on the role of explicitly political identities in pulling various political beliefs, attitudes, and perceptions into ideological alignment. This story, of course, starts with party identification.

Partisan identity. It makes sense to regard party identity as the key attribute that pulls diverse political idea elements into ideological packages. Parties are indispensable to democratic functioning, as they are the coalitions that channel individual preferences into organized collective action aimed at gaining power and realizing policy outcomes. When a citizen identifies with a party, they are psychologically aligning themselves with a coalition whose purpose is to harness the energy and desires of various groups to the goal of gaining political power. Indeed, many other social identities (such as those based on class or ethnic group) can exert their influence on political attitudes via identification with a party that is viewed as representing the interests and values of these social groups.

Partisan identity has, and still does, function as a “perceptual screen” that guides political thinking and underlies attitude constraint (Campbell et al., 1960). For example, panel data suggest that people adjust their political attitudes to match their party identities in the United States (Layman & Carsey, 2002; Carsey & Layman, 2006) and elsewhere (Harteveld et al., 2017; Slothuus, 2015; Slothuus & Bisgaard, 2021). Partisan identity also motivates individuals to rationalize their party’s stances by adopting beliefs that justify those stances (Bisgaard, 2019; Lauderdale, 2016; Tilley & Hobolt, 2011). Moreover, experimental data are consistent with citizens adopting the attitudes that political messaging cues indicate to be party-consistent (Arceneaux & Vander Wielen, 2017; Bisgaard & Slothus, 2018; Brader & Tucker, 2012; Druckman et al., 2013; Merolla et al., 2016). Thus, to the extent that opposed parties in a given political context offer ideologically distinct programs, all of these social motives associated with partisanship should promote more ideologically cohesive views among partisans (Abramowitz, 2010; Levendusky, 2009).

The most common explanations for the power of partisanship to structure political thinking invoke partisan motivated reasoning, or reasoning that is biased toward reaching party-congenial conclusions (Bakker et al., 2020; Leeper & Slothuus, 2014; Peterson et al., 2013). This brings up a key distinction between two explanations for how partisan identity functions: *instrumental partisanship* and *expressive partisanship* (Huddy, Mason & Aaroe, 2015; Huddy et al., 2018; see Fiorina, 1976; Hamlin & Jennings, 2018). According to the instrumental explanation, party identity reflects a running tally of the relative merits of the

parties, which is updated as individuals acquire new information. This view emphasizes motives for accuracy in the processing of political information. According to the expressive explanation, party identity is a social identity that varies in strength across individuals. To the degree that it is strong, it motivates people to engage in party-consistent political cognition, attitude formation, and activity. This view emphasizes “consistency” or identity-expressive motivation.

Huddy and colleagues have demonstrated the utility of the expressive view of partisanship in the United States (Huddy et al., 2015) and in multi-party European democracies (Huddy et al., 2018). This perspective suggests that party identification leads people to adopt party-aligned attitudes because they gain expressive satisfaction from doing so. In this way, expressive motivation to adopt party-consistent attitudes may be one source of ideological constraint in systems where competing parties offer ideologically distinct programs (Campbell et al., 1960; Converse, 1964). Others, however, note that people might gain expressive utility merely from reporting party-aligned views in a survey, while not actually holding these views with sincerity or acting on them in the real-world (Bullock et al., 2015; Bullock & Lenz, 2019). However, Malka and Adelman (2022) show that evidence for insincere responding on matters of strong partisan valence is quite limited, and that when expressive motivation is strong enough to make people misrepresent their views in surveys it is also likely to be strong enough to influence their real-world political behavior.⁸

Other types of political social identity. It is for good reason that party identity is the main focus in explanations of how political identities structure political thinking and guide political behavior. A major part of partisan identity’s power comes from the fact that it can subsume other identities that influence political attitudes, beliefs, and perceptions (e.g., Mason, 2018). Because parties are coalitions of groups, other social identities get baked into the partisan cake. Nonetheless, recent work underscores how shifting political contexts can change the independent importance of other types of political identities. Here we briefly discuss three other political identities that have potential to shape the content and structure of belief systems. These are identification with a revered leader, identification with salient and branded issue stances, and identification with an ideological label.

When people talk about partisan influences on political behavior, the term “partisan” is sometimes used broadly to reflect allegiance to something that is not the party per se but is strongly associated with it. A key example here is a revered leader who belongs to a particular party. Much research has addressed the importance of relationships between political leaders and citizens (Blondel, 1987; Caprara & Zimbardo, 2004; Kunst et al., 2019). Social identifications with groups, such as political parties, can result in strong feelings of relational identification with key leaders (Steffens et al., 2014). Moreover, according to “transformational” approaches to leadership (Weber, 1948), when leaders possess sufficient charisma they “not only direct, but actively transform, their followers’ attitudes and behavior” (Reicher, Haslam, and Hopkins, 2005). To Reicher et al. (2005), those who become influential leaders within a group organized around a social identity are those who “are in a position to supply information about the category definition.” In this way, identification with a political leader that offers a clear ideological package of positions, above and beyond identification with an associated party, has the potential to pull attitudes and beliefs into ideological alignment.

Space limitations preclude a widely inclusive review of this literature. But it will serve our purpose to briefly describe one example: in the United States, at the time of this writing,

many Republicans identified more with Donald Trump than with the Republican Party itself (Page & Elbeshbishi, 2021; Rummler, 2021). This mattered, as it impacted elite incentives for whom to align with in a conflict between the revered leader and other elements of the party establishment. The electoral incentives were quite clear, as the party adjusted by aligning further with Trump and weeding out anti-Trump elements. But Trump and his followers' identification with him, we would argue, altered the definition and content of conservative ideology itself (Drutman, 2020; Hopkins & Noel, 2022; Lewis, 2019). That is, social identification with Trump seemed to be quite important for pulling idea-elements into an ideology and binding them together with this identity so that they would be difficult to change. Kunst et al. (2019), for example, found that, among white Republicans, "identity fusion"—defined as a deep-seated feeling of oneness with a group or individual—with Trump was a far stronger and more reliable predictor of support for persecution of disfavored ethnic groups and political violence than identity fusion with the Republican Party was. Because of identification with Trump, these attitudes might come to figure more prominently in the American "conservative" package while (for example) support of democracy-promoting wars overseas might become less central to that package. Thus, identification with a revered leader can structure ideological belief systems independently of party identity.

Other "partisan" influences on political behavior have more to do with a salient, branded issue stance or a movement. Consider the "Leave" versus "Remain" divide over Brexit that began to consume British politics in 2015. Hobolt and her colleagues note the traditional view of affective polarization as pertaining to animosity directed at members of the opposing party, but showed that identification with a stance on Brexit, which cut across party lines, generated affective polarization and outgroup prejudice that were at least as strong as those associated with partisanship (Hobolt et al., 2021; Sorace & Hobolt, 2021). A similar phenomenon occurred with the Tea Party movement in American politics in 2010. Williamson, Skocpol, and Coggin (2011) noted how this movement provided a new source of identity for many Republicans that was "untethered from recent GOP baggage and policy specifics" and was built around a belief package focused on racially infused grievance against government assistance to "undeserving" elements in American society. This identity, while associated with the Republican Party, went beyond party in the broad sense and helped shift the ideological content of American conservatism. In fact, it served to distinguish a subset of Republican voters from the party establishment, energized the defeat of Republican establishment candidates, and presaged Trump's hostile takeover of the Republican Party (e.g., Parker & Barreto, 2013). Thus, identification with a salient issue stance or an associated movement can impact belief systems independently of party identity.

A third example pertains to symbolic identification with an ideological label. Right versus left, or conservative versus liberal, is a common way of discussing and interpreting political differences in many parts of the world (as noted above). Within the United States, ideological self-labeling—or symbolic ideology, to use the term discussed earlier (Ellis & Stimson, 2012)—does seem to promote adoption of identity-consistent attitudes (Devine, 2015; Malka and Lelkes, 2010; Mason, 2018). Knutson (1995) demonstrated the "absorptive power" of left versus right identification in western European countries, showing that this identification had retained its stable core meaning in the economic domain while absorbing wider cultural meanings over time. Knutsen's (1995) analysis suggests that ideological identification can be a force that pulls idea-elements into an ideology in a shifting political information environment, as "new meanings of left and right are added to the old

meanings.” Of course, as we have seen, symbolic identification with an ideological label is not all-powerful: many individuals who identify with a specific ideological category do not adopt the issue positions that follow from it (especially with regard to right-wing economic positions among self-identified conservatives; see Ellis & Stimson, 2012). Thus, identification with an ideological label can to some extent structure broader belief systems independently of partisan identity.

Finally, in a polarized environment where different social and political identities increasingly align along a single dimension of political conflict, it might make the most sense to speak in terms of “mega-identities” that structure ideological belief systems (Finkel et al., 2020; Mason, 2018). As we discuss later, many scholars express concern that the tendency to interpret all societal tensions and divisions in terms of conflict between overarching political identities is a danger to democracy in the United States (Drutman, 2020; McCoy, Simonovits, & Littvay, 2020) and other countries (McCoy et al., 2018; Slovik, 2019). Although these mega-identities encompass more than partisanship—they also incorporate ideological labels, reverence for prominent leaders, salient identity-conferring issue stances, and identification with social movements—the nature of parties is that they come to represent sides in these overlapping societal divisions, thus absorbing other sources of societal conflict into partisan conflict. Mason and Wronski (2018), for example, show that party identity in the United States, especially among Republicans, now represents a more broadly aligned set of social group memberships, which enhances its power to structure political thinking and define the content of liberalism and conservatism.

3.3. Deference to Trusted Elites as a Source of Ideological Constraint

In the previous section we noted how the desire to express a valued political identity—most often partisanship—can lead people to adopt attitudes and beliefs that match that identity, resulting in greater ideological cohesion when competing identities are ideologically differentiated. But while it is clear that many people adjust their attitudes to match those of their political “side” (e.g., their party, a revered leader), discerning the motives for doing so is a complicated matter. The desire to express one’s identity may not be the only operative factor. In this vein, a venerable tradition within political science depicts partisan cue-taking about issues as a form of effort-saving political rationality rooted in social trust (Lupia & McCubbins, 1998; Popkin, 1991; Sniderman et al., 1991). The key idea here is that if one trusts a set of political elites to hold reasonable or moral political stances (and distrusts the opposing set of elites), then it is rational to defer to these elites (or avoid the positions of the opposing elites) when forming attitudes and making political choices.

Tappin, Pennycook, and Rand (2020) recently addressed this issue. The type of design most often used to examine expressive, identity-based influences on belief systems is the “party cues” design, where participants are provided with information that a particular issue position is endorsed by their party or an out-party. Considering this design, Tappin and his colleagues (2020) note the following:

... party cues signify endorsement by a source that is either perceived as trustworthy and aligned with one’s interests (same party cue), or as untrustworthy and opposed to one’s

interests (opposition party cue). Thus, the information treatment alters perceived source trustworthiness. (p. 84)

Manipulations that provide party cues about an issue in an effort to causally identify the effect of expressive motives often violate the *excludability assumption*—that is, that the manipulation only alters the expressive reward associated with adopting one stance or another. Rather, they also alter whether one stance or another is thought to be most consistent with prior beliefs. That said, it is important to note these prior beliefs still pertain to social identity, as they are about trust or distrust of particular groups of elites on the basis of identity match versus mismatch. Thus, the effect demonstrated in cue experiments is social in nature regardless of whether expressive motives or rational reliance on trusted elites is at work.⁹ Either path can socially facilitate the formation of ideologically consistent preferences to the extent that parties and their leaders offer ideologically distinct sets of policy options.

To the degree that ideological constraint is rooted in deference to knowledgeable elites that one trusts on the basis of prior opinions, this suggests a normatively welcome role of accuracy motivation in the formation of ideological belief systems, even if reliance on trusted elites is heuristic in nature (Chaiken & Ledgerwood, 2012). In truth, it is likely that accuracy motives (i.e., those aimed at holding correct opinions) and consistency motives (i.e., those aimed at reaching identity-consistent conclusions) both impact political reasoning to some degree (Jerit & Kam, Chapter 15, this volume; Lavine et al., 2012; Groenendyk, 2013; Groenendyk & Krupnikov, 2021). Groenendyk (2018), for example, has argued that the present context of American polarization has heightened both the motive to adopt and justify identity-consistent attitudes *and* the motive to be open-minded and rational in the adoption of political attitudes. These motives conflict when one is presented with unfavorable information about one's own party, in which case accuracy motivation would favor accepting this information while consistency motivation would favor rejecting it. The solution, according to Groenendyk (2018), is to accept the unfavorable information about one's own party and to then further derogate the opposing party in one's mind in a "lesser-of-two-evils" political justification strategy. In the context of parties that are ideologically sorted at the elite level, this suggests that out-party elites might be more of a guide to what is ideologically inappropriate than same-party elites are to what is ideologically appropriate (e.g., Nicholson, 2012).

4. REVERSING THE CAUSAL ARROW: POLITICAL COMMITMENTS AS INFLUENCES ON NON-POLITICAL IDENTITIES

Traditionally, studies of traits, social identities, and political attitudes have modelled the latter as the dependent variable and traits and social identities as independent variables. This approach implies a clean delineation between individual differences in non-political constructs and individual differences in political constructs—and it assumes uni-directional causal influence of the former on the latter. Although this approach simplifies theorizing about ideology, it may fail to capture the nature of political worldviews in all circumstances.

In this section, we have emphasized that interpersonal experiences, social identities, and orientations toward the social world are what promote the binding of idea-elements into ideological belief systems. The power of social motives to do this comes from the fact that *political beliefs and attitudes are viewed as compatible with or inherently part of non-political identities and self-perceptions*. However, this logic implies that non-political identities and self-perceptions may themselves be adopted as a result of prior political commitments. In other words, it might make sense to conceptualize and operationalize ideological belief systems in a more encompassing way that includes both political and ostensibly non-political elements that are drawn together into alignment. Emerging work—which we review in this section—highlights the potential advantages of this approach.

For example, consider religiosity. The usual approach in political psychology is to assume that individual differences in religiosity exert a constraining influence on ideological affinity and other political preferences (Layman, 2001; Malka, 2013). Correlations between religiosity and conservative political attitudes are therefore assumed to reflect a unidirectional causal influence of the former on the latter. Patrikios (2008), however, used panel data from the United States to demonstrate that political commitments (party identification in particular) influence religiosity. Republican identity was associated with increased religiosity over time while Democratic identification was associated with the opposite. Margolis (2018a, 2018b) expanded on this by demonstrating that partisans with young children at home, who face a decision about whether and how religion should factor into their child-rearing, are particularly likely to adjust their level of religiosity on the basis of their partisanship. She concluded that “the strong association between religiosity and partisanship comes about, in part, because partisans adopt their party’s religious stances as their own” (Margolis, 2018b, p. 30).

What about other demographic identities? American partisan coalitions are to an important degree sorted on the basis of identities having to do with ethnicity, religion, sexual orientation, and class. Furthermore, many politically engaged people have an exaggerated view of how sorted the parties are with respect to these identities (Ahler & Sood, 2018). Because demographic identities correspond with group memberships that are costly or difficult to change, it is usually assumed that they are fixed attributes whose relationships with political attitudes exclusively reflect their causal influence on the latter. However, Egan (2020) recently noted that demographic identities can shift over time, both because they represent a subjective attachment to a group (as distinct from an objective group membership) and because people’s personal attributes sometimes position them at the boundaries of the group memberships that correspond with an identity. This raises the possibility that political commitments—including ideological ones—exert causal influence on the claiming of demographic identities. Indeed, using panel data from the United States, Egan (2020) found that small but significant segments of the American public change their ethnic, class, religious, and sexual identities to better match the prototypes of their partisan and ideological groups.

Finally, similar processes may be at work with respect to self-reported personality traits and self-perceptions. Due to their relatively strong rank-order stability in adulthood and their substantial heritable component, traits are often assumed to be causes, not consequences, of political commitments (cf. Hatemi & Verhulst, 2015). But it is possible that political commitments exert some causal influence on self-reported personality traits (Bakker et al., 2021). This might in part be because these commitments lead people to adopt

behavioral and experiential patterns that are stereotypical of their ideological or partisan in-group, or because they lead people to perceive themselves as similar personality-wise to the prototypical member of their political in-group. For example, Ludeke and his colleagues (2016) found evidence that people “overclaim” traits that characterize their ideological groups relative to the trait levels that would be expected on the basis of non-self-report indicators (e.g., peer reports). Similarly, some longitudinal evidence suggests that ideological and other preferences exert causal influence on personality traits, although these effects are small (Bakker et al., 2021; Boston et al., 2018; Luttig, 2021; cf. Osborne & Sibley, 2020). Finally, Bakker et al. (2021) found that individuals report personality traits that are slightly more congruent with their previously assessed political attitudes when politics is primed. All of this suggests that people are at least motivated to perceive their personalities as consistent with the prototypes of their ideological groups.

In sum, recent evidence suggests that the nature of the causal relationship between background characteristics and ideological affinity may be more complex than researchers have sometimes assumed. Ideology and other political identities may influence demographic identities and self-reported psychological dispositions, as well as being influenced by them. To be sure, the more complicated picture painted by this new evidence does not (in our opinion) imply that researchers should abandon the effort to identify causal antecedents of ideology. However, it does suggest that researchers may need to better contextualize relationships between demographics and personality, on the one hand, and ideology, on the other, as part of a broader, multidirectional network of causal effects.

5. IMPLICATIONS FOR POLARIZATION AND DEMOCRATIC FUNCTIONING

Scholars have long debated the precise importance of public opinion for democracy (Claassen, 2020; Dahl, 2008; Fails & Pierce, 2010; Lipset, 1959; Welzel & Inglehart, 2008). But public opinion influences the incentives of political elites to degrade or preserve democratic institutions and communicates the extent to which there exists support for mass action to degrade democracy (Malka & Costello, 2023; Graham & Svobik, 2020; Svobik, 2019; Sullivan, Piereson, and Marcus, 1983). Many of the insights about the nature of ideology that we have described in this chapter have implications for attitudes towards democracy and actions that degrade democracy. In this final substantive section of our chapter, we review them.

First, some of these insights bear on the long-running question of whether certain ideological groups are more likely than others to support democracy-eroding efforts. A classic view from psychology is that individuals oriented toward the right are the most anti-democratic (Adorno et al., 1950; Nilsson & Jost, 2020). However, many classical measures tapping anti-democratic sentiment are optimized for detecting right-wing forms of illiberalism (Malka et al., 2017), and changes in measurement strategies can be undertaken to assess individual differences in authoritarianism-related constructs that apply specifically to the left (Costello et al., 2021; Conway et al., 2016). Furthermore, intolerance might have more to do with rigid ideological commitment in general than with a broad-based right-wing or left-wing orientation (Crawford & Pilanski, 2014; Brandt et al., 2014; Zmigrod, 2020).

That being said, recent work has addressed whether right- versus left-wing preferences relate to preferences for authoritarian governance. In this work, support for authoritarian governance is measured in a narrow way that focuses strictly on lack of commitment to democracy and support for degrading democratic institutions and norms. Malka, Lelkes, Bakker, and Spivack (2022) addressed this question using data from 14 consolidated Western democracies and two distinct survey projects. Cultural conservatism consistently predicted openness to authoritarian governance, across all countries and with effect sizes typically exceeding those for college education, political engagement, and other oft-noted predictors of democracy attitudes. This finding was replicated in a pre-registered study with a large demographically representative American internet sample in September of 2020 (Malka & Costello, 2023). This is consistent with theoretical perspectives linking ethnic antipathy (Miller & Davis, 2021) and opposition to societal liberalization (e.g., Welzel, 2007) to anti-democratic views. It is also consistent with the possibility that underlying genetic factors and/or needs for security and certainty may bind together cultural traditionalism and authoritarianism (e.g., Ludeke et al., 2013).

However, desires for certainty and security relate to left-wing attitudes in some domains for substantial subsets of citizens, as noted previously (Johnston et al., 2017; Malka et al., 2014), and needs for security and certainty often give rise to a “protection-based” attitude configuration representing a combination of cultural traditionalism and redistributive economics (Malka et al., 2019). This suggests that a combination of right-wing cultural preferences and left-wing economic preferences might be uniquely associated with a high level of anti-democratic sentiment. Indeed, Drutman et al. (2018) found this in American data, and this finding replicated in all of the English-speaking countries (Australia, Britain, Canada, New Zealand, and the United States) in the aforementioned study using World Values Survey and Latin American Public Opinion Project data (Malka et al., 2022) as well as the aforementioned pre-registered replication in 2020 (Malka & Costello, 2023). Increasingly, evidence suggests that within the United States and other English-speaking countries, there is something about the protection-based belief-system configuration that coheres with anti-democratic sentiment (e.g., Carmines et al., 2016; Lefkofridi & Michel, 2017; Lipset, 1959).

A second way in which insights about ideology relate to public opinion regarding democracy has to do with the social aspects of ideological constraint. As we have argued, the extent to which ideological conformity is enforced in social and interpersonal contexts is often underappreciated. The interpersonal importance of toeing the ideological line may combine with the fact that an individual’s political behavior usually has no meaningful instrumental consequences in the broader world to make political behavior mainly about relationship maintenance and identity expression (Hamlin & Jennings, 2011; Kahan, 2015a; Robbett & Matthews, 2018). If shared reality with close others is at stake, then there are serious obstacles to ideologically committed people defying anti-democratic actions undertaken by ideologically aligned elites and peers.

In the United States, surveys reveal worrying growth in anti-democratic sentiment (Drutman et al., 2018; Malka & Lelkes, 2017). These concerns are intimately tied to mounting affective polarization and the growth of social networks that are increasingly homogenous in political terms (Drutman et al., 2019; Drutman, 2020; Graham & Slovik, 2020; Malka & Costello, 2023; McCoy et al., 2020). A common explanation for this increase in anti-democratic sentiment is that viewing the other side as existentially threatening can lead

citizens to prioritize keeping opponents out of power over a commitment to the democratic process (Graham & Svolik, 2020; Svolik, 2019). But, as Malka and Costello (2023) note, it is also important to recognize how the absorptive power of ideologically-relevant identities can lead people to incorporate and justify elite-cued messages, including rationales that justify anti-democratic actions as pro-democratic. In this vein, research indicates that a considerable number of citizens simultaneously support democracy in the abstract and favor authoritarian actions under-taken by their side (Drutman et al., 2019; Inglehart, 2003). This asymmetry suggests that the beliefs incorporated into ideologically-relevant identities may allow individuals to believe that effectively authoritarian actions by one's side actually serve to "protect" democracy (Malka & Costello, 2023).

Acknowledgment of the social and interpersonal factors behind the coherence of ideological belief systems highlights the challenges faced by efforts to reduce partisan animosity and potential threats to democracy via messages and interventions (e.g., Feinberg & Willer, 2013; Lees & Cikara, 2020; Levendusky, 2018). First, if adoption of identity-consistent beliefs serves the goal of fitting in and getting along in one's social surroundings, then the effects of a countervailing message are unlikely to survive the recipient's return to their normal social surroundings and its associated messages and incentives. Rather, the attitude or belief promoted by the message would have to be continually socially reinforced, and this would require a change in incentives, and therefore messaging, from trusted political elites. Second, if people are motivated to identify with attributes that are prototypical of their ideological group, this should over time enhance perceptions that political opponents are fundamentally different, alien, and threatening (Bakker et al., 2021; Margolis, 2018a; Mason & Wronski, 2018). Third, if trusted elites present self-serving authoritarian actions as actually serving to protect democracy, then this belief will likely be absorbed into broader ideological postures, particularly for culturally conservative groups (Malka & Costello, 2023). As long as trusted ideological and partisan elites have political incentives to be divisive and to rationalize anti-democratic actions, counter-vailing efforts to reduce polarization and anti-democratic sentiment through messaging face an uphill battle.

6. CONCLUSION

In his chapter on ideology from the previous edition of this Handbook, Feldman (2013) emphasized the complexity involved in drawing connections between the character of ideology at the elite level and that at the mass level. Any notion of what "ideology" is at the mass level, Feldman observed, must be reconciled with findings suggesting multiple attitude dimensions that are not ideologically aligned for many people, low levels of attitude constraint, and largely unstable issue preferences. Indeed, if one defines ideology as a consistent, stable network of related beliefs and attitudes about the social and political world, Converse's (1964) conclusion that most of the public is "innocent of ideology" (while extreme in tone) would appear to remain more accurate than inaccurate (Kinder & Kalmoe, 2017).

That being said, among the most reliable findings in political psychology is that those segments of the population who are politically engaged are more likely to hold temporally stable political attitudes that are consistently aligned along the left-right dimension

(Baldassari & Gelman, 2008; Malka et al., 2019; Zaller, 1992). Moreover, these individuals are more likely to display traits, values, and identities that are aligned with these political attitudes. If ideology represents a system of interconnected political attitudes and beliefs—even if they are not necessarily connected as a result of consistent application of abstract ideological principles—then an important, highly active segment of the population is in fact functionally ideological.

In this chapter we have reviewed findings about the nature and origins of ideology among ordinary citizens and the social nature of the motives underlying the coherence of ideological belief systems. We leave the reader with two key take-home points that we believe can be helpful in guiding research on ideology. The first, which we emphasized in a previous review (Federico & Malka, 2018), is that links between underlying psychological attributes and ideological preferences are usefully viewed as varying along a continuum (Johnston et al., 2017; Malka & Soto, 2015). At one end of this continuum are “menu-independent” relationships that are organic and functional, meaning the political preference *directly* helps satisfy the underlying psychological needs represented by the attribute. At the other end of this continuum are “menu-dependent” relationships that are *indirectly* present only because the relevant political attitudes happen to be discursively packaged with other attitudes that organically relate to the psychological attribute. Distinguishing such menu-independent and menu-dependent relationships between psychological attributes and political attitudes is important for gaining a realistic understanding of how basic psychological orientations and processes attract people to specific political coalitions and their associated ideologies. It is also important for integrating perspectives that emphasize the durable, psychologically rooted features of ideology (e.g., Duckitt & Sibley, 2009; Jost et al., 2003, 2009) with perspectives emphasizing the flexible, socially constructed aspects of ideology (e.g., Hopkins & Noel, 2022; Lewis, 2019; Noel, 2014).

Our second take-home point is that the social motives that facilitate the coherence of ideological belief systems have an under-appreciated implication. The ideologically congruent attitudes, beliefs, and self-perceptions that people are motivated to adopt need not be limited to the political realm. Indeed, many attributes thought to exert unidirectional causal influence on political attitudes—such as religiosity, demographically rooted social identities, and personality traits—might also be pulled into alignment with a political orientation (Bakker et al., 2021; Egan, 2020; Ludeke et al., 2016; Margolis, 2018a; Patrikios, 2008; Sidanius, Kteily, Sheehy-Skeffington et al., 2013). In other words, the social and psychological forces that bind political attitudes into ideological belief systems might simultaneously pull non-political identities, self-perceptions, and even behavioral propensities into their event horizon when those ostensibly non-political characteristics are deemed ideologically congruent in a polarized context. This matters because it can infuse political conflict with greater cultural and personal meaning and increase animosity against political outgroups. The clean delineation of psychological attributes as causes and ideological belief systems as effects may thus be unwarranted.

NOTES

1. Qualifying this somewhat, it is important to note that valuing of equality applies to both the cultural and economic policy domains (Federico & Malka, 2018; Malka et al., 2017) and

- that a reliable link between a general and consistently applied orientation toward change and substantive aspects of left-right ideology is questionable (Proch et al., 2019).
2. Drift-diffusion modeling uses accuracy and reaction-time data from cognitive tasks as input and derives latent variables reflecting different aspects of cognitive performance, including average rate of evidence accumulation, how individuals balance speed versus accuracy, and speed of stimulus processing and response execution (Zmigrod et al., 2021, p. 3).
 3. For contrasting perspectives on this asymmetry, see Jost et al. (2017b), Azevedo et al. (2019), and Hennes, Nam, Stern, and Jost (2012).
 4. As a caveat, however, some recent measures of left-wing authoritarianism correlate more weakly with left-right self-placement than parallel (and older) measures of right-wing authoritarianism (Costello et al., 2021), suggesting that symmetry in authoritarian hostility is not perfect.
 5. Indeed, Zmigrod (2020) argues that rigid, defensive adherence to doctrine and a strong tendency to differentiate between political friends and foes may be constitutive of ideological thinking in general.
 6. Dispositional and situational forms of rigidity may also work together in complex ways. For example, while trait rigidity predicts conservative identifications, it also appears strengthen political identifications on both the right and the left (given that there is residual variance in rigidity among both left and right identifiers; Luttig, 2018; Zmigrod et al., 2020).
 7. Of course these classic findings about putative social transmission must now be considered in the context of evidence that political attitudes have substantial genetically heritable components (e.g., Smith et al., 2012), especially among individuals high in political sophistication (Kalmoe & Johnson, 2021).
 8. Other work, described later, focuses on the roles of accuracy motives and rational updating in partisan cue receptivity.
 9. Guay and Johnston (2020) designed experiments to overcome this confound and still found a substantial amount of politically motivated reasoning, and approximately equal levels of this among conservative and liberal identifiers (see also Ditto et al., 2019).

CHAPTER 18

MORALITY AS THE ENDURING BASIS OF PUBLIC OPINION

PAZIT BEN-NUN BLOOM

1. THE MORAL COMPASS

"A few crowning postures serve as a sort of glue to bind together many more specific attitudes and beliefs, and these postures are of prime centrality in the belief system as a whole"

(Converse, 1964, 211)

WHILE seminal works in political psychology have shown that voters are often politically ignorant and ideologically unsophisticated (Campbell et al., 1960; Converse, 1964; Delli Carpini & Keeter, 1996), there is also evidence that individual-level political attitudes are reasonably predictable, and that public opinion is overall stable and intelligible (e.g., Page & Shapiro, 1992). Consequently, a great volume of work in political psychology is aimed at discovering what guides people in constructing intelligible political attitudes.

One potential answer is the thesis of the moral public, which contends that in forming opinions on political matters, we are guided by moral values (Ben-Nun Bloom, 2010, 2013). Individuals hold enduring moral beliefs, in the sense of value-based systems pertaining to right and wrong; and these fundamental core beliefs can account in part for their positions toward more transient issues. This chapter reviews morality as the enduring basis of public opinion.

For many years, political psychologists have neglected morality as an enduring source of political attitudes and political behaviors. This is partly because the moral psychology literature was traditionally dominated by a view of moral judgment as governed by a cognitive reasoning process organized as a series of hierarchical stages (Kohlberg, 1969; Piaget, 1965). To study moral judgments, cognitive moral developmentalist theorists examined how individuals justify their responses to stylized moral dilemmas, such as Kohlberg's

famous Heinz dilemma.¹ To argue that moral judgments underlie the formation of political attitudes seemed to demand the assumption that citizens have the cognitive abilities and intrinsic motivation to scrutinize politics through the abstract and complex prism of moral principles.

Moreover, unlike stylized moral dilemmas in philosophy and developmental psychology, such as Kohlberg's Heinz dilemma and the trolley problem (Foot, 1967; Thomson, 1976),² many everyday moral dilemmas—and most if not all political debates—are multidimensional and complex, involving uncertainty, a dynamic informational environment, and multiple competing values that must be prioritized. Researchers traditionally believed that to empirically study the extent to which the public relies on morals when forming political attitudes, they must identify the array of specific moral rules that people may apply to a particular political issue. And this is not an easy task. In the absence of comprehensible moral principles, and the presence of contrasting theories of ethics, firm moral stances on specific political issues are extremely hard to derive (Hampshire, 1983; MacIntyre, 1988; Sartre, 1977; Williams, 1985).

Moral decision making may be less complex than imagined, however. In contrast to the traditional view that moral judgment is governed by an effortful cognitive reasoning process, recent empirical evidence supports a simpler view. This new approach is inspired by Hume's (1960) classic view of moral judgment as rapid, emotional, and intuitive (Cushman et al., 2006; Greene et al., 2004; Haidt, 2001; Koenigs et al., 2007). This framework facilitated a renewed focus on morality as a basis for political reasoning within political psychology. A moral compass guided by moral sentiment and intuition suggests a consistent and stable basis for public opinion even in the absence of political information, as many political issues can be reduced to questions of right and wrong. This novel conceptualization yielded renewed scholarly interest: an empirical analysis of social psychology journals shows a massive increase in the number and impact of publications on morality published from 2005 onward (Ellemers et al., 2019).

Still, rather than converging on particular perspectives and operationalizations, the morality literature seems to add new concepts and measures by the day. This review will help readers navigate through the abundance of definitions in this multidisciplinary literature, offering a guidebook to the moral compass. The chapter thus starts by reviewing the plethora of theoretical definitions for morality and "moral issues" in politics (section 2). The next sections discuss some of the complexities of the morality–politics nexus and reviews the main findings in this burgeoning literature. It describes the moral mindset as a primary explanation for key political behaviors, such as political mobilization, and for the political polarization and culture wars seen in contemporary democracies. In that vein, section 3 reviews central characteristics of moral attitudes, including their endurance and resistance to change, and their utility as issue frames. Section 4 further examines the links between moral attitudes and ideology, and in particular, possible ideological asymmetry in moral thinking. Section 5 discusses morality as a central mobilizing force: an important source of elite rhetoric, a vehicle for political activism, and a key dimension in voter evaluations of politicians. This is followed by a discussion of measurement (section 6). The chapter concludes (section 7) with some thoughts about the future of the field.

Table 18.1 Key terminology

Concept	Definition	Key measure
Moral dilemmas	Situations that encompass conflicting moral rules for individuals (Broeders et al., 2011).	E.g., the trolley problem and Kohlberg's Heinz dilemma (Foot, 1967; Thomson, 1976)
Moral judgment	"The evaluation of an act as morally wrong or right" (Ben-Nun Bloom, 2014, p. 496).	E.g., How morally permissible or morally impermissible is [act]? (Ben-Nun Bloom, 2014)
Moralization	A process that "involves the acquisition of moral qualities by objects or activities that previously were morally neutral" (Rozin, 1999).	See Rhee et al. (2019) for cross-sectional experimental and longitudinal approaches to moral change
Moral issues	Issues under debate that are regarded by at least one side as concerning or threatening its core values (Haider-Markel & Meier, 1996; Mooney, 2001).	Measures examine whether morality was applied to the dilemma according to a certain theoretical perspective (e.g., harm appraisal, moral intuitions, moral principles, moral conviction, moral emotions).
Moral domain	Principles within the moral domain have an intrinsic effect on the well-being of others; violating them causes harm and is thus inherently wrong. The intrinsic "harmfulness" makes moral principles universal, unalterable, and authority-independent. In contrast, the conventional domain pertains to arbitrary social rules (Turiel, 1983).	Tailored questions regarding allowing/prohibiting practices independent of rules and authority (see Turiel et al., 1991; Ben-Nun Bloom, 2013, 2014; Smetana, 2006)
Moral intuitions	Unconscious, sudden, and rapid emergence of a moral judgment, including an affective valence (Haidt, 2001).	Measured via dumbfounding moral dilemmas (e.g., Haidt, 2001) or more typically with the Moral Foundations Questionnaire (MFQ; Graham et al., 2011)
Moral emotions	"Emotions that are linked to the interests or welfare either of society as a whole or at least of persons other than the judge or agent" (Haidt, 2003, p. 853).	(Haidt, 2003; see also Lefebvre & Krettenauer, 2019)
Moral foundations	Innate psychological mechanisms that dictate moral judgments on what constitutes right and wrong. These mechanisms differ among people, and include five moral systems: Harm/Care, Fairness/Reciprocity, Ingroup/Loyalty, Authority/Respect, and Purity/Sanctity.	MFQ30; MFQ20 (Graham et al., 2009, 2011)
Moral conviction	"The belief that a given attitude is a reflection of one's core feelings or beliefs about fundamental issues of right and wrong" (Skitka et al., 2021, p. 348).	2-item self-reported moral conviction measure (Skitka et al., 2005)
Core values	"Transsituational goals, varying in importance, that serve as guiding principles in the life of a person or group" (Cieciuch et al., 2015).	SVS-57 items (Schwartz, 1992); PVQ-21 items (Schwartz, 2003)

2. WHAT MAKES A POLITICAL ISSUE A MORAL QUESTION? THEORETICAL PERSPECTIVES ON MORALITY IN POLITICS

The first step in exploring the role of morals in public opinion is to identify what political issues are understood in moral terms. However, scholars employ vastly different theoretical frameworks to study moral issues, suggesting a plethora of definitions (and consequent measures; see section 6). This section organizes the main approaches to the study of morality in politics by clarifying the most essential terminology: morality policies, domain theory, sentimentalism, moral foundations, and moral convictions (see also Table 18.1).

2.1. Morality Policies: Moral Issues as “Hot-Button” Social Problems

Classic political science literature suggests that certain “moral” issues, such as abortion and same-sex marriage, display signature patterns of political decision-making and public responses that render them inherently different from other, “non-moral” (e.g., economic) issues. Scholars working within this approach typically identify a moral issue in a top-down manner, by examining “how an issue is framed, rather than its intrinsic content” (Mooney & Schuldt, 2008). A moral issue within this framework is one where “at least one advocacy coalition involved has portrayed the issue as one of morality or sin,” and “used moral arguments in its policy advocacy” by exposing its embodied fundamental value conflict (Haider-Markel & Meier, 1996; Mooney, 2001). Such “politics of sin” is characterized by a refusal to compromise or to settle for a mere decline in sinful behavior, instead battling for total abolition (Meier, 1999). These “morality policies,” as they are known, are therefore effectively viewed through the lens of religion (Engeli et al., 2012).

This typology is helpful in explaining the role of moral issues in politics. It explains why morally framed issues are at the heart of voter mobilization, candidate preferences, and party alignment (Adams, 1997; Hillygus & Shields, 2005; Layman et al., 2006). It also allows us to derive typical characteristics of moral issues: controversial, publicly salient, simple to grasp, and revolving around social conflicts rather than disagreement on material interests (Heichel et al., 2013; Hillygus & Shields, 2005; Mooney, 2001).

Looking for elite moral discourse as a way to classify issues as moral is particularly useful when comparing sets of political issues (e.g., social vs. economic issues), election cycles (e.g., the moralization of environmental politics), political parties (e.g., to see which employs more elite moral rhetoric on a given issue), and countries and times (when and where issue are moralized and how this translates into partisan cleavages). Still, this approach has significant limitations. For instance, the definition is somewhat endogenous, lacking *a priori* criteria for political issues likely to generate such value-based conflicts (Heichel et al., 2013). Further, moral framing may fluctuate in keeping with elite strategic and contextual considerations (Mucciaroni, 2011), and the public may not be tuned in to these changes. At the individual level, research works suggest that morals can be potentially applied to any

issue, whether complex or mundane, and not excluding economic issues (Kertzer et al., 2014; Ryan, 2014).

Most importantly for political psychologists, despite the centrality of the top-down approach within the political science literature, this perspective is less useful when seeking to analyze individual-level moralization, as opposed to the societal or group level. Consider, for instance, the issue of pornography regulation. A top-down examination will clearly identify this as a moral issue. In countries that have attempted to pass legislation limiting access to online pornography—including the United Kingdom, France, Australia, Ireland, and Poland, to name but a few—moral arguments are certainly employed by elites in policy advocacy, often with visible “politics of sin” dynamics. However, do all citizens uniformly view regulation of online porn as a moral issue?³ What does it mean to view this issue morally? Does it entail employing a certain kind of logic or particular principles when reasoning about porn regulation? Does it mean viewing pornography as harmful, or revolting, or “just wrong,” making regulation morally imperative? The various perspectives on morality in political psychology, described below, each offer a different idea of what it means to view a political issue through a moral lens (also see Table 18.1).

2.2. Domain Theory: Moral Rules Concern Harm, and Are Thus Universal, Authority-Independent, and Unalterable

The influential social-cognitive moral domain theory (hereinafter: “domain theory”) developed by Elliot Turiel (1983) builds on the pioneering stage theories of Kohlberg (1969) and Piaget (1965) (for an overview of political socialization research see Sears & Brown, Chapter 3, this volume). Global stage theories within the structural-cognitivist Kohlbergian heritage view moral reasoning as a series of hierarchical cognitive stages acquired in a fixed order starting at a young age, indicating moral development. Like stage theories, moral domain theory views morality as a constructivist process in which morality is acquired by children in their daily social interactions. Yet, unlike global stage theories, morality is not viewed as hierarchical, and types of social knowledge are not thought to be acquired in succession, making some judgments more “morally developed” than others. Rather, beginning in early childhood, children distinguish between types (i.e., domains) of social knowledge, and particularly between societal norms, psychological preferences, and morals (Helwig & Turiel, 2002; Nucci, 2001; Turiel, 1998).

What differentiates the moral domain from the domains of social conventions and personal preferences? Following the Rawlsian approach, actions within the moral domain are seen to have intrinsic effects on others’ well-being, rendering violations—that is, harm to the physical or psychological welfare of others—inherently wrong (Dworkin, 1978; Rawls, 1971). As such, the moral domain encompasses rules and actions involving harm, justice, and rights (e.g., “never engage in unprovoked hitting,” or “women should be allowed to vote”), which are “categorical in that what persons ought to do sets requirements for them that they cannot rightly evade by consulting their own self-interested desires or variable opinions, ideals, or institutional practices” (Gewirth, 1978, p. 24). The domain of convention contains rules of right and wrong as well, but as derived from social norms, authority, and tradition (e.g., stopping at a stop sign). Thus, social conventions are arbitrary: they hold

force through the social organization they define, and can be changed at will (Nucci, 2001; Turiel, 1983). While the existence of a social regulation is necessary for an act to be regarded as a conventional transgression, social regulation is unnecessary for an act entailing intrinsic harm to be regarded as a moral transgression.⁴

This non-arbitrary nature of moral rules, which distinguishes them from arbitrary social-personal conventions, is defined by at least three formal criteria: (1) universality, (2) authority-independence, and (3) unalterability. Consider the rule “children should not be tortured.” The attribute of *universality* or *generalizability* (versus *relativity*) suggests that transgressions in the moral domain are judged to be wrong and impermissible across social contexts. If you think that intentionally inflicting severe pain on children to obtain information is always wrong, in any place or time, then for you this rule is universal. *Authority-independence* suggests that transgressions are wrong even in the absence of a specific law against such behavior, or even if the governing authority is unaware of the violation or chooses not to prosecute it. *Unalterability* suggests that moral obligations should not be alterable by means of any political or social mechanism—that is, torturing children is morally wrong even if allowed by referendum (see Smetana, 2006). If all three criteria hold for this rule in your eyes, then you categorize it as wholly in the moral domain.

Applying domain theory to politics, the extent to which political issues are judged as moral issues varies at the individual level with assumptions about the extent to which transgression is perceived to entail harm to others’ welfare (e.g., Ben-Nun Bloom, 2010; Turiel et al., 1991). For instance, pornography consumption may be classified in the moral domain for some, given assumptions about harm (e.g., the potential exploitation of performers), but in the conventional domain for others (who consider performers to be consenting adults). Nonetheless, as suggested by the morality-policies framework, political issues are expected to differ in their likelihood of being considered a matter of morals, with some political issues more likely to be categorized in the moral domain. For example, the intentional harm to an individual that characterizes capital punishment makes it more likely to be judged as universal, authority-independent, and unalterable than issues such as agriculture funding.

A large body of literature supports the moral domain perspective by confirming that people distinguish moral obligations from social conventions and personal issues above and beyond stimuli, settings, and cultures (for reviews, see Nucci, 2001; Smetana, 2006; Turiel, 1998). What is more, this robust distinction emerges at a very young age. For instance, Smetana (1981) reports that children as young as three years old recognize moral transgressions such as shoving and hitting as generalizably wrong and rule-independent, as compared to conventional transgressions such as not sitting in a designated spot or not returning toys to their places.

2.3. Sentimentalism and Intuitionism: Moral Issues Activate Moral Emotions

Critics of domain theory dispute its Rawlsian postulate that the moral domain universally concerns matters of others’ welfare: harm, justice, and rights. Haidt et al. (1993) suggest that if the moral domain uniquely involves matters of harm and rights, then reassuring a person that an action was clearly harmless to others (and not related to violations of rights or injustice) should lead them to unambiguously classify it in the conventional-personal domain.

To test this, they craftily invented and presented taboo violations—that is, masturbating into a dead chicken before cooking and serving it for dinner, or a one-time consensual and secretive incest event with no long-term psychological costs—to samples of American and Brazilian children and adults. They then showed that despite persistent reassurance that no one was harmed in these scenarios, participants (with the notable exception of upper-class American adults) still insist on judging such taboo violations as immoral. The fact that people stick with their moral judgments despite their inability to reason through their judgment by attributing harm to the transgression is termed “moral dumbfounding” (Haidt, 2001).

Haidt’s moral dumbfounding results notwithstanding, domain theory’s premise that people of all ages across cultures distinguish between morals and conventions based on certain formal properties is backed up by persuasive and robust evidence. What is it, then, if not overt harm to others, that allows toddlers of three to distinguish between moral and conventional rules, such that the former are judged as more serious, generalizably wrong, and rule-independent? Emotion is an excellent candidate.

Indeed, Haidt observed strong emotional responses of participants to taboo violations. Accordingly, his Social Intuitionist Model (SIM) de-emphasized the role of moral reasoning implied by stage and domain theories. Following the primacy of affect research tradition (Zajonc, 1980), the SIM model suggests that more often than not, an automatic intuitive reaction emerges in response to moral transgressions, and it is this affective response that shapes our moral judgment; when cognitive moral reasoning occurs at all, it is a post hoc process destined to justify a preceding intuition (Haidt, 2001, 2003, 2012; for an overview of political emotions research see Brader and Gadarian, chapter 6, this volume).⁵

Surely not all emotion-generating acts are regarded as moral in nature, however. Sorrow at missing a loved one or anger at discovering a parking ticket on the windshield do not indicate that broken hearts and parking inspectors are regarded as immoral. For sentiment to explain classification into the moral domain, moral emotions must be distinguished from conventional ones. Haidt (2003) defined moral emotions as “those emotions that are linked to the interests or welfare either of society as a whole or at least of persons other than the judge or agent,” with prototypical moral emotions including disgust, anger, contempt, guilt, and shame.

Yet while the criterion of domain attribution may be too restrictive, excluding acts that do not entail harm (e.g., the taboo-violating sexual habits studied by Haidt et al., 1993), a criterion based on prototypical moral emotions (disgust, anger, contempt, and so on) may not be restrictive enough. Many acts elicit prototypical moral emotions, but only a subset of them are immoral (recall your anger at the parking inspector). A more restrictive conceptualization of moral emotions in politics suggests that what differentiates moral from conventional rules is not just the type of emotion (anger vs. sadness), but also whether the act holds potential to evoke both other-directed and self-directed emotions (Prinz, 2008). Both criteria are necessary to ensure the generalizability of the moral norm: if you are angry with a parking officer who issues you a ticket, yet would not feel ashamed, in his position, to issue such tickets to others, then for you issuing a parking ticket is not a moral transgression (Ben-Nun Bloom, 2013, 2014).

The sentimentalist view of morality is corroborated by empirical evidence. Moral cognition has been amply demonstrated to be tied to core affect, and specifically to emotions such as revulsion, anger, contempt, guilt, and compassion (Cameron et al., 2015; Haidt, 2012; Hutcherson & Gross, 2011; Rozin et al., 1999). Neuroscience research, including work using imaging technology, has shown that moral cognition is linked to brain regions responsible

for processing emotion (Decety & Cacioppo, 2012; de Oliveira-Souza et al., 2015; Horberg et al., 2011). Similar findings have come from studies with patients suffering from brain damage in areas related to emotions (e.g., Koenigs et al., 2007; Moretto et al., 2010), and with psychopaths, who are characterized by affective deficits (Blair et al., 1997).

Some adherents of the sentimentalist perspective, including the SIM model, have argued that people are hard-wired through evolution to respond with certain emotions to certain moral transgressions (Haidt, 2012). Notably, Rozin et al. (1999) found empirical evidence for what they termed the CAD triad hypothesis (also see Cheng et al., 2013; Haidt, 2012; Horberg et al., 2011; Russell & Giner-Sorolla, 2013). Building on work by Shweder et al. (1987), they showed that transgressions in each of three moral domains—community (relating to communal values), autonomy (individual rights), and divinity (sanctity and purity)—give rise to a basic moral emotion: contempt for community, anger for autonomy, and revulsion for divinity.⁶ However, more recent reviews of the evidence on morality and emotions suggest no systematic evidence for a link between discrete emotions and moral content (Cameron et al., 2015).

Overall, current evidence suggests that the SIM model may underestimate the role of reasoning in moral judgment. The fact that it is difficult for people to identify immediate harms in certain taboo acts—incest between consenting adults, unusual self-pleasing, or eating your recently deceased pet dog—does not mean that they do not conceive of these acts as causing harm, whether to social institutions, to tradition, or to the agents in their afterlife (Ben-Nun Bloom, 2010). Further, there is evidence that participants perceive moral dumbfounding scenarios as carrying the *potential* to bring about harm, even if no harm was caused in the particular case (Stanley et al., 2019; but see McHugh et al., 2020). It has also been found that when asked to justify moral transgressions, people spontaneously use deontological (rule-based) appeals to a much greater extent than emotive justifications (65% vs. 22%; Wheeler & Laham, 2016). Finally, even if moral deliberation drives moral judgments less frequently than emotion, it still plays a key role in politics: it is moral debate rather than moral emotions that underlies changes in public opinion over time.

Accordingly, some literature in political behavior combines domain theory and sentimentalism perspectives by showing that both reasoning and emotions underpin moral domain categorization in political settings. This integrative position follows the literature on dual processes in psychology, suggesting that moral judgments can be guided by an immediate intuitive or affective automatic process, or by a more controlled, effortful, and reasoned appraisal (Greene, 2013; for a review of dual process theory, see Jerit & Kam, Chapter 15, this volume). In particular, studies demonstrate that moral convictions and moral judgments in politics are causally affected both by harm associations, as domain theory would argue, and by moral emotions (e.g., Ben-Nun Bloom, 2013; 2014; Schein et al., 2016; Wisneski et al., 2020).

2.4. Moral Foundations Theory

While Haidt's results and SIM theory suggest that the moral domain does not universally entail harm to others and rights violations, this line of work leaves open the question of what content constitutes the moral domain. Haidt's Moral Foundations Theory (MFT; Graham et al., 2009; Haidt & Joseph, 2007) was developed to fill this gap.

MFT draws heavily on Shweder et al.'s (1987) "three ethics" of autonomy, community, and divinity. Richard Shweder, a cultural anthropologist and Haidt's former teacher, had set out to disprove Elliot Turiel's universalist domain theory, arguing instead for a pluralist and "moderately relativist" approach toward morality, based on the belief that moral values fall into different, sometimes competing domains (e.g., justice vs. care; Shweder & Haidt, 1993). Together with colleagues, Shweder has argued that moral domain theory can be disproven by showing systematic cross-cultural differences in how people identify and respond to moral issues (Shweder et al., 1987). If the matters included in the moral domain vary systematically between cultures, then by definition they fail the tests of both universality and authority-independence, but instead are contingent upon social institutions.

Examining what practices are thought to be moral (i.e., perceived as universal, unalterable, etc.) among Americans and Indians, Shweder and his colleagues found that many of the issues classified by domain theory in the realm of social-personal conventions—such as questions relating to appropriate food, clothing, and sex roles—were in fact classified by Indians as matters of morality. This led the researchers to the conclusion that the content of the moral domain is variable across cultures.⁷ Accordingly, they suggested that human moral phenomena fall into three domains, rather than one. The "ethics of autonomy" concerns rights, freedom, and individual welfare; as such, it is most like the universalistic moral domain posited by domain theory. The "ethics of community" concerns one's obligations to the larger community, such as loyalty, duty, respectfulness, modesty, respect for hierarchy, and self-restraint. Finally, the "ethics of divinity" is concerned with the maintenance of moral purity and sanctity.

Paralleling the debate in virtue ethics about which character traits constitute virtues, moral foundations theory sought to augment this list of potential moral domains. MFT suggests that human systems of morality evolved through the ages in response to fundamental social challenges. MFT then takes an inductive approach to define the main categories governing the moral domain. In this vein, Haidt and colleagues reviewed the anthropology and evolutionary psychology literature to identify the "top candidates for being the psychological 'foundations' upon which cultures construct their moralities" (Graham et al., 2011, p. 6). They proposed five sets of intuitions underlying moral judgments (Graham et al., 2009; Graham et al., 2011; Haidt & Joseph, 2007):

- 1) Harm/care. This moral foundation evolved to motivate caring for the vulnerable and allowing for kin altruism. It is related to the virtue of kindness and the emotion of compassion.
- 2) Fairness/reciprocity evolved to allow cooperation with individuals who are not kin. It is related to the virtues of justice and trustworthiness and the emotions of anger, gratitude, and guilt.
- 3) Ingroup favoritism/loyalty evolved to allow group cooperation in the presence of competition for resources. It is related to the virtue of patriotism and the emotions of group pride, belongingness, and hostility toward traitors.
- 4) Authority/respect evolved to allow the emergence of hierarchies, wherein superiors maintain order and protect subordinates, who in turn show deference and respect. It is related to the virtue of obedience and the emotions of respect and fear.
- 5) Purity/sanctity evolved to facilitate the avoidance of parasites and bacteria. It is related to the virtues of temperance, chastity, piety, and cleanliness, and the emotion of revulsion.

After proposing this list, Haidt and his colleagues posted a challenge on their website offering a prize of \$1000 “to anyone who could show that additional foundations were needed or that the current foundations should be rearranged.” This led to various candidates being proposed, among them liberty/oppression, pertaining to the virtue of autonomy and focusing on libertarian objections to governmental coercion, which was added as a sixth foundation (Iyer et al., 2012). This additional foundation, however, has received less attention in the political psychology literature.

Based on empirical results, MFT suggests that the five main moral foundations can be grouped into two dimensions: the *individualizing* moral foundations of harm/care and fairness/reciprocity, which focus on the individual and correspond to Shweder et al.’s (1987) ethics of autonomy; and the group-focused *binding* moral foundations, including ingroup favoritism/loyalty, authority/respect (both corresponding to the ethics of community), and purity/sanctity (corresponding to the ethics of divinity). As is the case with possessing a virtue, adhering to a given moral foundation is a matter of degree. For instance, a person may adhere strongly to the binding moral foundations, prioritizing such values as patriotism, group pride, and respect for group leaders, while treating the individualizing foundations as secondary (though still valuing them to a certain extent) (for discussion on the link between moral foundations and political ideology see Federico & Malka, Chapter 17, this volume).

As will be evident throughout this chapter, a burgeoning literature has adopted MFT’s assumption that morality extends beyond concerns with harm and fairness, using its typology and measurement system to study a wide range of political behaviors—including political attitudes (see section 3), ideology (section 4), and elite rhetoric (section 5). At the same time, MFT has been criticized for its ad-hoc nature (e.g., Hatemi et al., 2019; Smith et al., 2017), over-inclusiveness (Schein & Gray, 2015), relatively weak generalizability across cultures and groups (e.g., Davis et al., 2016; Iurino & Saucier, 2018), and particularly the validity of its measurements, as will be elaborated in section 6. Still, a review by Ellemers and colleagues (2019) shows that MFT has become the dominant approach to morality in psychology, producing by far the most cited works. In fact, there are some empirical indications that Jonathan Haidt has almost singlehandedly revived the interest of political and social psychologists in moral judgment and its relationship with politics.

2.5. Morality as an Attitude Attribute: Moral Conviction

A final perspective sees morality as an attitude attribute. This approach contrasts with those reviewed above, which seek to standardize the boundaries of the moral domain by pre-defining what qualifies as moral—whether via domain characteristics, particularly harm (Schein & Gray, 2015; Turiel, 1998), or through a broader conceptualization which views the moral domain as categorized into five or six foundations (Graham et al., 2009). Rather, this approach relies on people’s own perceptions of their cognition as morally charged (Lovett & Jordan, 2005). Central to this paradigm is the concept of moral conviction, “the belief that a given attitude is a reflection of one’s core feelings or beliefs about fundamental issues of right and wrong” (Skitka et al., 2021, p. 348), as measured by self-reports. For instance, studies may ask respondents whether or not their judgment on an issue, such as abortion, is “a reflection of your core moral beliefs and convictions” and “connected to your beliefs about fundamental right and wrong.”

A moral conviction is viewed as an individual attribute of an attitude, which one may hold to varying degrees, alongside (i.e., controlling for) other attitude dimensions such as certainty, extremity, and importance (Skitka et al., 2005; but see Philipp-Muller et al., 2020). The assumption is that individuals can access their psyches to apply their idiosyncratic conceptualization of what is moral in order to report the level of morality that they assign to a given position (Skitka et al., 2021); and that these self-reports capture their moral judgment in a way that enables meaningful comparisons between people and groups. Ample studies within this perspective show that people may potentially view any political issue through the lens of morality, including economic issues that other perspectives may view as inherently non-moral in nature (Ryan, 2014).

What does self-reported moral conviction capture? First, moral convictions have been found to be correlated with emotions—not with moral emotions in particular, but rather with scaled positive/negative emotions or a host of discrete emotions such as pride and regret (e.g., Skitka et al., 2016; Skitka & Wisneski, 2011). Moral convictions are also linked with skin conductance, indicating emotional arousal (Garrett, 2019). Additionally, moral conviction has been correlated with theory-driven elements of domain theory, such as universalism and perceived objectivity (Skitka et al., 2021). However, emotions are viewed within this perspective as better predictors of moral convictions than are domain theory appraisals or harm perceptions (Brandt et al., 2016; Clifford, 2019; Feinberg et al., 2019; Skitka et al., 2017).

To conclude, this section presented the dominant perspectives on morality in the contemporary political psychology literature, focusing on the conceptualization of moral issues in politics. Clearly, conceptualizing the moral domain in politics is complex. I propose to view each of the perspectives as capturing different elements of moral judgments, and thus as suitable to study different research questions. This approach treats the various perspectives as complementing each other rather than competing. To better decide which of these approaches may fit well with your own research question, you may want to carefully examine their operationalization of moral judgments. In that vein, section 6 is devoted to the different approaches to measuring morality in the context of public opinion.

The next three sections review how the various approaches are used to explain key political behaviors: political attitudes and attitude change (section 3), ideological asymmetry in moral judgments (section 4), and political mobilization, including elite rhetoric and candidate evaluations (section 5).

3. MORALITY AND ATTITUDES: ATTITUDE STRENGTH, ATTITUDINAL CHANGE, AND MORALITY AS A SOURCE OF PSYCHOLOGICAL CONSTRAINT

While some attitudes serve an instrumental function, stemming from a motivation to gain rewards and avoid punishment, attitudes based in morality serve a value-expressive function, fulfilling people's need to establish and express their own self-definition (Katz, 1960; Rokeach, 1968). Attitudes rooted in moral values tend to be stronger than conventional or utilitarian attitudes. This makes such attitudes more resistant to political persuasion, while also making moral framing a good vehicle for political persuasion under certain circumstances. Finally, morality can also serve as a psychological constraint holding

together a meaningful belief system, and thereby weakening the Conversion view of the public as dysfunctional and ideologically unconstrained. This section begins to probe how morality might serve as the basis of public opinion by examining how moral convictions translate into political attitudes.

3.1. Morality and Attitude Strength

Attitudes vary in persistence and resistance (Petty & Krosnick, 1995). Literature from multiple perspectives converges in associating morality with attitude strength, showing that a moralized attitude is held with greater certainty (and less ambivalence), is cherished as more important, and is more extreme (Ben-Nun Bloom, 2013; Brandt et al., 2016; Philipp-Muller et al. 2020; Skitka et al., 2005).

There are several reasons why moralized attitudes are experienced as more certain. Tying a political object to the harm schema implies viewing it as intrinsically wrong under all circumstances. This increases the tendency to generalize this stance when assessing new information, thus reinforcing the existing attitude. When activated, moral emotions contribute to attitude certainty as well. They color all aspects of the situation (Mullen & Skitka, 2006), rendering us relatively insensitive to the situation's particulars (Bartels & Medin, 2007), and augmenting the existing standpoint as the experience is revisited. People thus become predictably biased in their decision-making (Taber & Lodge, 2006).

A sense that one's attitude is important is another symptom of a moralized attitude. Attitudes that are based upon closely held moral values establish one's self-concept and identity (e.g., Rokeach, 1968) and are sometimes called *ego-involving attitudes* (Ostrom & Brock, 1968). Since an attitude derived from a moral position exerts an involvement of the self that is less likely to arise in the case of conventional attitudes, it increases the perceived importance of a successful outcome in any debate.

Attitudes rooted in morality are also likely to be more extreme. This is because a moral stance is not amenable to compromise (Hunter, 1991; Meier, 1999; Mooney & Schuldt, 2008; White, 2002), and moral debates cannot easily be resolved by reference to new facts (Engeli et al., 2012). Evidence also shows that people express more extreme and rigid moral judgments when emotion is induced (Greene et al., 2001; Trafimow et al., 2005). Moreover, attitudes also become more extreme the more they are reinforced through repeated expression, whether in one's mind or verbally (Petty & Krosnick, 1995). People are more likely to repeat and reinforce attitudes as they grow in perceived importance and certainty, resulting in a further increase in extremity.

It should be noted that while moral convictions are conceptually and empirically associated with attitude strength, a moral conviction regarding a political object is typically described as a distinct attitude attribute. For instance, self-reported moral convictions still hold explanatory power even with the effect of attitude strength partialled out (Skitka et al., 2005). Another study showed that both moral conviction and attitude strength have independent effects on political attitudes, holding each other constant (Ryan, 2017). It has also been suggested and demonstrated, using a two-stage-least-squares model building on experimental instruments, that attitude moralization affects the strength with which one holds the attitude, rather than the other way around (Ben-Nun Bloom, 2010, 2013). Likewise, moral conviction loaded on a dimension of attitude embeddedness in core values

together with additional attitude properties such as importance and certainty (Philipp-Muller et al., 2020).

3.2. Morality and Attitude Change

“Disputes with men pertinaciously obstinate in their principles, are, of all others, the most irksome,” writes David Hume in his *An Enquiry Concerning the Principles of Morals*. People with moralized attitudes are expected to have “blind adherence to their own arguments . . . contempt of their antagonists . . . and . . . passionate vehemence, in enforcing sophistry and falsehood” (1960, p. 7). Indeed, a moral mindset amplifies the resilience of individuals facing situations that promote attitude change, such as those wherein there is sweeping support for the other view (Aramovich et al., 2012; Conover & Miller, 2018). Overbearing efforts to promote change in an audience fortified with a moral mindset may even backfire and direct the target audience away from the recommended attitude change (Ben-Nun Bloom & Levitan, 2011; Täuber & van Zomeren, 2013). Still, studies also find that moral messages can facilitate attitude change in the persuasion-suggested direction compared to non-moral messages on a host of issues, from same-sex marriage to universal health care and torture (e.g., Arceneaux, 2012; Clifford & Jerit, 2013; Day et al., 2014; Feinberg & Willer, 2015). The extent to which attitude change is boosted or attenuated under a moral mindset is intimately related with the way morality enters into political considerations.

Morality can enter the thought process to ultimately affect political attitude change through the preexisting mindset of the message recipient—whether the recipient sees the object of the discussion in a moral light or not⁸—and through the characteristics of the persuasive appeal. Moral appeals are messages or persuasion attempts that are imbued with moral cues. Morality can be imbued in the message through moral framing—that is, integrating moral argumentation or language. Morality can also be imbued in persuasive appeals through the message being conveyed by a moralized source (messenger) or within a moralized setting (both typically regarded as moral priming), holding the content constant.⁹ Importantly, there is an interaction between the two—the mindset of the target audience and the characteristics of the message—in affecting attitude change.

Let us consider the moral mindset first. As discussed above, attitudes rooted in personal morals tend to be highly unbending, meaning that attempts at persuasion may be hard to press. Indeed, even labeling an attitude as moral can make people more resistant to changing their view (Luttrell et al., 2016; Petty & Krosnick, 1995). Again, this is partly because moral convictions exert an involvement of the self that is less likely to arise in relation to conventional attitudes (Ostrom & Brock, 1968, p. 375). The morally motivated individual may thus perceive a moral counterargument as posing a threat not only to her moral attitude, but also to her self-concept and sense of identity (Haugtvedt & Wegener, 1994; Johnson & Eagly, 1989; Ostrom & Brock, 1968). A moral mindset also renders people relatively impervious even to the persuasive effect of their own social network (Ben-Nun Bloom & Levitan, 2011).

Still, persuasion can be more successful when it considers the extent to which the target audience moralizes the issue in question. The classic functional matching hypothesis (Katz, 1960) suggests that a persuasion attempt will be more successful to the extent that it directly addresses the psychological function underlying a given attitude. That is, by addressing the individual’s underlying motivation, the message generates interest, facilitates processing,

and directs attention toward the attitude's relevant attributes. A number of studies support this "moral matching" hypothesis, according to which moral appeals are particularly persuasive for target audiences that moralize the discussed political issue.

In support of this view, Lavine and Snyder (1999) showed that value-expressive messages increase recommended attitude change (e.g., encouraging people to vote). More recently, Bayes et al. (2020) showed that a message framing climate change in terms of conservative moral values was effective in changing beliefs and intentions concerning climate change among Republicans experimentally induced with a threat to their moral values. Similarly, moral appeals about antirecycling and marijuana legalization were more persuasive than non-moral appeals to the extent that initial attitudes were based on moral rather than practical concerns (Luttrell et al., 2019).

People are also motivated to protect their pre-existing attitudes. Thus, a political message can be framed in terms of a moral appeal designed to match the specific prior attitudes, for instance by reframing a moral argument in terms of binding moral foundations for conservatives (Wolsko et al., 2016) or drawing on religious language for a religious audience. Research using the MFT framework to examine support for pro-environmental legislation found that appeals framed in terms of purity (vs. harm) were more persuasive to conservatives (Feinberg & Willer, 2012) and increased recycling among conservatives (Kidwell et al., 2013). Such effects may be mediated by the belief that the matched moral frame is being expressed by a member of the ingroup (Wolsko et al., 2016).

In addition to matching the message to the function (moral or practical) and content (type of value) of the audience's preexisting attitude, other techniques can reduce the persuasion-resistance of morally convinced recipients. Particularly, it was found that two-sided messages acknowledging the recipient's moral position have a persuasive advantage when recipients base their attitudes on their morality compared to counter-attitudinal one-sided messages (Xu and Petty, 2021).

Moral framing can be used not just to shift people's attitudes, but also to reinforce existing behaviors. Here, the realm of social media offers useful lessons, with potentially far-reaching implications for the public discourse. For example, one study of Twitter messages concerning polarizing issues found increased diffusion of tweets containing moral-emotional language, such that sharing increased by roughly 20% on average for every additional moral-emotional word. However, importantly, the effect on retweet rates was larger within political ingroup (rather than outgroup) networks, suggesting that "communications about morality are more likely to resemble echo chambers and may exacerbate ideological polarization" (Brady et al., 2017). Likewise, moral framing was found to increase the sharing of news stories on Facebook and Twitter in Chile (Valenzuela et al., 2017), and was related to the probability of social movement messages being retweeted and favorited at the time of the 2019 Hong Kong protests—though again, the direction of the effect was contingent on the moral dimension used in the tweets and on support for the movement (Wang & Liu, 2021). Still, current research warns against placing too much trust in the correlations revealed in large social media datasets (Burton et al., 2021). To demonstrate the need for caution, it shows that a moral contagion model, which posits that the use of moral-emotional language will increase the spread of messages, does not yield significant improvement over an implausible XYZ contagion model. Finally, one interesting question is how moral framing—that is, imbuing a message with moral cues—works at the cognitive level. There are reasons to believe that moral persuasion affects cognitive processing. Certainly,

it appears that moral framing, when effective, transforms how the target conceives of and reasons about the morally imbued information. For instance, in one study, moral appeals—employing value-based rather than pragmatic rhetoric—increased the likelihood of the target later employing moral argumentation in justifying their political decision (Colombo, 2021). The literature suggests three different routes by which moral framing or priming may affect the target's cognition. First, the origin of the message (e.g., a religious figure, trusted authority, friend, or political candidate) may influence the target's perception of whether the messenger is being honest (or, conversely, manipulative), and the degree to which the message may be biased (Ben-Nun Bloom & Levitan, 2011; Wallace et al., 2019). This may affect meta-evaluative processes, independently of the specific content of the persuasive message. Second is whether the target processes the message through a central-effortful or peripheral-intuitive cognitive route (Petty & Cacioppo, 1986). Targets who employ central-effortful processing apply a high level of metacognitive scrutiny to the message. This may lead them either to further validate the message, or to “correct” the potential influence of the appeal (e.g., Briñol & Petty, 2009). Finally, certain moral emotions, such as disgust, may impede learning and thereby reduce engagement with the message (Clifford & Jerit, 2018).

3.3. Moral Attitudes and Psychological Constraint

Moral attitudes can also be viewed as those political attitudes wherein a moral belief system serves as a psychological constraint. According to Converse (1964), belief systems are dynamically constrained if a change in one's attitude toward one issue is necessarily accompanied by a change in attitude toward a related issue. These horizontal constraints, wherein attitudes on related political issues are connected to each other, derive from a vertical constraint, wherein both are connected to some abstract superordinate belief or ideology (see Converse, 1964, p. 211; Peffley & Hurwitz, 1985, p. 872). Thus, support for women's rights should be correlated with support for legalizing abortion, and both attitudes should in turn make one more likely to defend the rights of other marginalized groups (horizontal). In turn, support for women's rights, legalizing abortion, and marginalized populations may all be derived from a higher guiding principle, such as social equality and egalitarianism (vertical).

Converse postulated that constraint is learned from political and social agents, who regularly communicate the shared structures of liberal and conservative ideology. For this reason, this approach is often referred to as *sociological* constraint. Building on this assumption, he found little evidence for constraint among ordinary citizens, whose attitudes are less organized by a “proper” ideological view as communicated by ideological elites. However, others have advanced a *psychological* view of constraint, according to which constraint in political attitudes can stem from within the individual's psyche, and thus is likely to differ between individuals. When conceptualized in this more idiosyncratic manner, coherence in political attitudes should not be measured by how well they mirror elite ideology, but rather by how consistently they follow a certain set of inner concepts, which vary between people. If this is the case, then Converse's famous gloomy view of the non-ideological citizenry—or rather, public *non*-opinion—is at least partially a consequence of his search for the wrong type of constraint.

While the literature discusses several sources of psychological constraint, particularly personality traits (Jost et al., 2003), moral values are a good candidate to serve as a key source of individual-level constraint in how people derive their political attitudes. More

often than not, values and morals are proposed to underlie ideology rather than the other way around (Feldman, 1988; Lakoff, 2002; Schwartz, 1992). A sense of morality is readily available to us from a very young age (Smetana, 1981), potentially from infancy (Wynn & Bloom, 2014), whereas abstract political attitudes emerge at a later developmental stage. This is because formulating such abstract attitudes requires a comprehension of core political concepts—for example, war, state, nationality, institutions, norms, and laws—that only develops during adolescence (Piaget & Weil, 1951; Torney-Purta, 1990). Given the moral nature of many political debates, and their rootedness in questions not of empirical facts but of right versus wrong, visceral moral reactions—feelings of disgust, guilt, or anger, or a strong sense of wrongness and harm—may lead people to respond consistently to groups of political issues, as well as promoting stability in people's political attitudes.

Thus, for researchers and practitioners, moral judgments are not just a meaningful and significant predictor of public opinion on specific issues. Rather, an inquiry based on moral judgments can also reveal the key sources of constraint within the political belief system of a particular individual (or group) about a particular political object, and thereby weaken the Conversionian view of the dysfunctional, “ideologically innocent” public. Finally, this discussion can also go some way toward explaining why moral framing and persuasion, however well a position is argued, may face an uphill battle in changing people's attitudes in a climate of political moralization.

4. IDEOLOGICAL ASYMMETRY IN MORALITY

While providing normative relief by weakening the Conversionian view of the dysfunctional public, the idea of psychological constraint complicates systematic study of the ideology-moral judgment nexus. A range of abstract concepts can potentially guide us in politics, and there is no guarantee that different groups are guided by the same concepts (e.g., Conover & Feldman, 1981). Thus, an issue may be moral—meaning that transgressions typically lead to a sense of harm or feelings of revulsion—for conservatives but not liberals, or the other way around. Equally, individuals and groups may derive their attitudes from moral judgments for some issues, sociological constraints for others, and personality traits for still others. Moreover, people may view different issues through different prisms at different times. For instance, consider recent concerns over government surveillance and threats to individual privacy. One may view such questions through the lens of preventing harm to the individual (“the individual right to privacy is sacrosanct”)—until the emergence of a terrorist threat, when one may adopt an authoritarianism prism.

Given the dynamic and complex nature of psychological constraints, systematic analysis of the ideology-moral judgment nexus may be guided by three competing hypotheses. First is the possibility that different ideological groups (i.e., liberals and conservatives) differ in their respective tendencies to perceive core political issues as moral (the “moralizing conservatives” hypothesis). Second is the possibility that liberals and conservatives are equally likely to view political issues through a moral perspective, but perceive politics through differing moral lenses (“conservatives are from moral Mars, liberals from moral Venus”). Finally, the “morality for all” hypothesis suggests that all individuals generally rely on similar moral criteria regardless of their ideology—although conservatives and liberals may apply a moral lens to differing political objects. Each of these hypotheses is supported by evidence, though not all studies conceptualize morality the same way.

4.1. The “Moralizing Conservatives” Hypothesis

The theory behind the “moralizing conservatives” hypothesis contends that American conservatism since the 1990s has been strongly associated with support for traditional moral and religious values (Miller, 1994). Accordingly, Republicans have successfully claimed moral standing for their positions on many issues and have generally done a better job communicating their messages in moral terminology (e.g., Lakoff, 2002). This may imply that conservatives today are more concerned with moral issues, and hold stronger moral convictions, than do liberals.

Some scholars ground the “moralizing conservatives” hypothesis not in such top-down moralizing, but in individual attributes. This explanation argues that individual propensities drive a conservative tendency to moralize and a liberal tendency to “conventionalize.” Indeed, conservatism has been found to be related to dogmatism and to intolerance of ambiguity, avoidance of uncertainty, and the need for cognitive closure (Jost et al., 2003), all of which underlie a need for a rigid categorization of the world—something that is achieved by looking at the world in terms of right and wrong (Bakker reviews this literature in Chapter 2, this volume; see also Federico & Malka, Chapter 17, this volume). Rigid morality is also viewed as a conservative response to an uncertain world (Jost et al., 2003, p. 347). Liberals, on the other hand, are often viewed as more reluctant to judge based on right and wrong.

Regardless of which mechanism prevails, some studies based on exit polls have found that moral values are the main reason for voting among conservatives (e.g., 80% among Bush voters; see Media Matters, 2004). Consistent with these results, Lovett and Jordan (2005) showed that Bush voters in the 2004 presidential election scored higher in measures of moralism—that is, the “tendency to perceive everyday life as imbued with a moral dimension” (Lovett & Jordan, 2005, p. 167)—than did Kerry voters. If this view is correct, it has implications for campaigns, persuasion, participation, and electoral success, based on the fact that morality serves the motivational role of increasing action tendencies (Wren, 1991). Specifically, it implies that conservatives are easier to mobilize and more willing to participate and vote, giving an inherent electoral advantage to conservative candidates.

4.2. “Conservatives Are from Moral Mars, Liberals from Moral Venus”

The second hypothesis holds that while conservatives may not by definition rely on morals to a greater extent than do liberals, they may apply morals in a qualitatively different manner, perceiving politics through different moral lenses. Accordingly, it has been proposed that liberals and conservatives differ in their moral language. Theorizing on the image of the “nation as family,” Lakoff (2002) suggests that liberal elites moralize about politics by evoking a nurturing family, while conservative elites evoke the metaphor of a strict father figure. The differing moral concepts behind these metaphors—care on the one hand, authority on the other—then guide their respective constituencies in political matters. Janoff-Bulman and Carnes (2013, 2016) critiqued the prediction of the “moralizing conservatives” hypothesis that only conservatives engage with moral concerns at the group level, suggesting that while conservatives are concerned with social *order*, liberals focus on social *justice*.

Similar reasoning can be applied using moral foundations theory. Here, the argument is that liberals and conservatives care most deeply about differing moral foundations: liberals

are most concerned with the individualizing foundations of care (avoiding harm to others) and fairness (justice and equality), while conservatives are concerned with the three binding foundations—loyalty (being loyal to the ingroup), authority (respecting authority, hierarchy, and tradition), and purity (respecting sanctity or wholesomeness)—alongside care and fairness (Graham et al., 2009, 2011; Haidt, 2012). According to MFT, while all five foundations are available at birth, a child's moral mind is socialized to view the world through either an atomistic and optimistic lens, or one that is community-oriented and pessimistic. The former is reflected mainly in the individualizing foundations, while the latter cannot be expressed without the binding foundations (Graham et al., 2009, 2011; Joseph et al., 2009).

This prediction of MFT has found at least partial evidence. Different levels of concern with individualizing versus binding moral foundations (for liberals and conservatives respectively) have been tied to political attitudes on a host of issues, from abortion to pornography (Koleva et al., 2012), candidate selection (Clifford, 2018; Franks & Scherr, 2015), and intentions to participate politically (Johnson et al., 2014). For instance, sermons in liberal versus conservative church congregations were found to employ more themes relying on the harm and fairness moral foundations and on binding foundations, respectively (Graham et al., 2009).

4.3. “Morality for All”

Some studies examining MFT's prediction of ideological asymmetry suggest that while some political differences between liberals and conservatives in moral judgments may exist, they generally rely on similar moral criteria. Recently, Frimer (2020) examined religious contexts as well as political, media, and organizational settings in an attempt to replicate Graham et al.'s (2009) results, according to which liberal and conservative sermons differed in their use of moral language. They found only weak support for increased use of purity and authority words among conservatives, suggesting that “it would probably be more accurate to conclude that liberals and conservatives use similar moral languages than that they use different languages” (Frimer, 2020, p. 13).

Further challenging the “moral Mars vs. moral Venus” hypothesis, Hatemi et al. (2019) suggest that moral foundations seem more likely to be situational assessments made to justify preexisting ideological beliefs, rather than a robust explanatory framework of political orientations. In contrast to the argument discussed earlier that values and morals underlie ideology rather than the other way around (Feldman, 1988; Lakoff, 2002; Schwartz, 1992; see section 3.3), they argue that ideology is more stable than moral foundations assessments, and is more likely to predict Moral Foundations Questionnaire (MFQ) responses than to be predicted by them. Still others suggest that when ideological differences in moral concerns are found to be present, they can be attributed to personality differences, particularly to systematic ideological variance in right-wing authoritarianism (RWA) and a social dominance orientation (Federico et al., 2013; Kugler et al., 2014; Milojev et al., 2014). For instance, Kugler et al. (2014) suggested that RWA fully accounts for the ideological differences in authority, in-group loyalty, and purity as predicted by MFT.

Other studies also depart from the “moral Mars vs. moral Venus” approach in that they argue that liberals and conservatives generally rely on similar moral criteria—but with an interest in differing political objects. For instance, conservatives and liberals alike were

found to employ sacred language from the domain of purity: conservatives when justifying social attitudes (e.g., on same-sex marriage), and liberals when justifying environmental protections (Frimer et al., 2017).

If indeed, as argued by the “morality for all” hypothesis, conservatives and liberals rely on a similar moral structure but apply it to different political issues, the question arises: what types of issues are moralized by liberals vs. conservatives? Frimer (2020) suggests that liberals tend to moralize issues pertaining to social justice and the environment, while conservatives do the same for religious and military issues. By another account, differences in how liberals and conservatives moralize issues are mediated by evaluations of the harmfulness of the practice (Ben-Nun Bloom, 2010). Specifically, liberals almost exclusively moralize issues that entail harm to people, whereas conservatives also moralize issues where they perceive harm to the social order (i.e., through violations of norms, traditions, and institutions). As such, it was found that the two issues on which liberals held the greatest moral convictions at the time were torture and capital punishment, where people’s physical well-being is intentionally compromised, while the two most important moral issues for conservatives were gay adoption and abortion, where core family and religious values are at stake (Ben-Nun Bloom, 2010). Future studies can examine social issues that have gained prominence more recently, such as the Black Lives Matter movement, critical race theory, and rights for transgender individuals.

As a final note, the relationship between morality and ideology may depend on the conceptualization of ideology and on the political context. A recent meta-analysis focusing on the relationship between moral foundations and ideology supports the expected pattern by which the binding and individualizing foundations are related to right- and left-wing ideologies, respectively, but suggests that this pattern is more typical of social rather than economic issues, and is moderated by political culture (Kivikangas et al., 2021). More work is needed to assess the morality-ideology link in different contexts. First, the issues moralized, the level of moralization, and the creed associated with “left” versus “right” are all contingent on the particular point in time and on the examined culture. Second, most studies on morality and ideology are conducted in the United States, where ideology typically reflects a unidimensional left-right contrast. In other countries, however, ideology includes an economic as well as a social vector, and these may relate to morality in different ways. Relatedly, most studies apply a self-reported single-item measure of ideology, which may conceal complexity in the morality-ideology link.

5. MORALITY AND MOBILIZATION: ELITE MORAL RHETORIC, CANDIDATE EVALUATIONS, POLITICAL PARTICIPATION, AND INTOLERANCE

Elite moral rhetoric portrays the political debate in terms of right and wrong, often with the hope of mobilizing voters. This section will first examine the levels and types of elite moral rhetoric and will then consider the effect of moralization of politics on three key political processes: political participation, political polarization, and candidate evaluations.

Although normatively inverse in nature, both political participation and political intolerance have morality as a common denominator, with strong moral emotions such as anger, disgust, and contempt as the main underlying micro-mechanisms. Finally, when elites employ morality as a key evaluative criterion in politics, it will inevitably be used by voters to evaluate them as well. This section will thus conclude with the use of morality in candidate evaluations.

5.1. Elite Moral Rhetoric

At a time when political dialogue in the United States and Europe increasingly frames issues in moral terms, several theories propose that the weight placed on moral matters is what underpins current political divisions (Ben-Nun Bloom, 2013; Cahn & Carbone, 2010; Callahan, 2007; Frank, 2004; Hunter, 1991). In particular, it is often argued that polarization dynamics are driven by party conflicts over what constitutes desirable moral values (Evans, 1997; Hetherington, 2009; Layman et al., 2006). As elites align on moral issues and adopt polarized positions, constituents soon follow suit (Adams, 1997). Put differently, when political discourse boils down to “right” and “wrong,” and elites use different kinds of moral language in appealing to different constituencies, voters become more set in their opinions, and impossible to persuade. This in turn leads to political deadlock and even further polarization.

Evaluating patterns in elites’ use of moral language is typically done through content analysis, relying on moral language lexicons developed based on one of the theories of morality, usually MFT (e.g., Graham et al., 2009; Neiman et al., 2016). Results from these analyses with regard to ideologically asymmetrical use of moral language are mixed, and highly sensitive to the time and issue examined (Frimer, 2020).

For instance, using the MFT dictionary, Clifford and colleagues (Clifford et al., 2015; Clifford & Jerit, 2013) examined the use of language reflecting the harm and purity moral foundations in national media content on the debate over stem-cell research. Their findings suggest that purity rhetoric is employed to a greater extent in content reflecting the anti-stem cell position, and harm rhetoric in content reflecting the pro-stem-cell position. Similarly, newspaper ads discussing environmental issues were found to engage the harm foundation in particular (Feinberg & Willer, 2012). However, an analysis of speeches and television interviews by Republican and Democratic politicians did not support MFT’s expectation of differential moral language (Neiman et al., 2016). Studies testing Lakoff’s expectation of a differential breakdown in “strict father”/“nurturing parent” rhetoric in presidential election television spots also yielded mixed results (see Moses & Gonzales, 2015; Neiman et al., 2016; Ohl et al., 2013).

Likewise, an extensive analysis of Democrats’ and Republicans’ use of moral language in tweets and speeches found that conservative elites in the United States do not necessarily reference the binding foundations more than their liberal counterparts. In fact, in tweets posted from 2016 to 2018, Democrats used more moral language than Republicans across all moral foundations. Importantly, however, an analysis of speeches along a much longer period (1981–2017) shows that the difference in moral language use systematically changed over time based on party control, such that minority-party members used more moral language (Wang & Inbar, 2020). Interestingly, a study

analyzing English language books from 1900 to 2007 documents vast historical shifts in the cultural salience of the various moral foundations (Wheeler et al., 2019). It is thus currently unclear whether the same psychological mechanisms underlie moralization at the elite and public level.

Regardless of whether theoretical expectations of ideological asymmetry in the use of moral language are ultimately found to hold, it is clear from another group of studies that the use of elite moral language is effective in increasing mobilization, particularly public engagement within social media. For example, studies have found that the use of a moral-emotional frame increases the diffusion of messages by federal politicians (e.g., presidential candidates, members of the Senate and House) on Twitter (e.g., Brady et al., 2017; Valenzuela et al., 2017). Further, this “moral contagion” effect was stronger for conservative elites (Brady et al., 2019; but see Burton et al., 2021).

5.2. Political Participation

Morals are often viewed as intrinsically action-guiding and as motivations in and of themselves (see Wren, 1991). One mechanism behind morality’s action-oriented role may relate to its association with affect. Evidence in the psychology literature points to the primacy of affect in motivating behavior, and the key role of emotions in increasing the probability of a decision to act (Zajonc, 1984). In fact, some scholars classify an emotion as moral based, *inter alia*, on their motivation induction and action tendencies (Haidt, 2003). Certainly, it makes sense that people who hold an emotionally laden moral conviction on a given issue should be more motivated to take action to promote their view—that is, to engage in political life.

The role of morality as a motivating force for political participation can also be attributed to the value-expressive function of moral convictions, and the overwhelming drive to protect one’s ego in the face of challenge. Finally, there is the sheer ease of applying morals to politics. Moral issues are typically highly salient, and studies on morality policies suggest that people are willing to act on such issues based on very little information, leading to greater citizen mobilization and individual-level participation (Haider-Markel & Meier, 2003).

Empirically, the relationship between a moral state of mind and participation intentions, such as voting and activism, is well established in the literature. For example, in the context of the refugee crisis in Hungary, moral convictions were related both to volunteering to help refugees and to formal political engagement (Kende et al., 2017). Moral concerns also underlie participation in boycott and buycott efforts—that is., efforts to change corporate or national policies by, respectively, eschewing or deliberately seeking out particular products or suppliers (Fernandes, 2020). In addition, moral language was found to be associated with more indirect behavioral measures of political engagement, such as sharing news stories on Facebook and Twitter (Brady et al., 2017; Valenzuela et al., 2017; Wang & Liu, 2021).

A moralized attitude may be weighted more heavily when appraising a candidate’s or a party’s appeal and may even be the only dimension evaluated in making voting decisions, a phenomenon known as “issue voting” (Congleton, 1991). In issue voting, voters focus solely or primarily on issues about which they both care the most, and feel the greatest understanding and certainty. Indeed, both emotional indicators of attitude moralization and

reasoned indicators based on domain-theory characteristics have been found to increase issue-based political participation, as well as a tendency toward issue voting (Ben-Nun Bloom, 2013).

One interesting question is the degree to which moral concerns underlie political participation in an ideologically asymmetrical manner. Based on a meta-analysis, Skitka et al. (2015) proposed that the relationship between moral convictions and participation intentions (e.g., voting and activism) is robust and characterizes both the left and the right. However, the motivational values underpinning political behavior may differ for different ideological camps. In keeping with the expectation that liberals and conservatives are concerned with different sets of moral foundations, Fernandes (2020) found that liberals boycott and boycott to protect the individualizing moral foundations of harm and fairness, whereas conservatives do so to protect the binding foundations of authority, loyalty, and purity.

5.3. Intolerance and Polarization

The past two decades have seen a shift in the political atmosphere, characterized by increasing ideological extremism and polarization. The emotional nature of moral convictions may explain these processes. Experimental evidence shows that people become more intolerant of moral transgressions and tend to express more extreme and more severe moral judgments when emotion is induced (e.g., Trafimow et al., 2005; van Stekelenburg & Gaidytė, Chapter 26, this volume). It has been found that partisan moral conviction—wherein our attitudes about political parties, party leaders, and party members are connected to our fundamental sense of right and wrong—has led to an increase in affective polarization in the United States. Individuals who tend to moralize politics exhibit more partisan bias, distance, and hostility, irrespective of their partisan strength and ideology (Garrett & Bankert, 2018). In fact, the “culture war” is often defined by its portrayal of emotional morality, as a “political and social hostility rooted in different systems of moral understanding” (Hunter, 1991, p. 42).

Indeed, there is empirical evidence that a moral mindset is related to several indicators of intolerance. Self-reported moral conviction is associated with social distance, such that some individuals are decreasingly willing to maintain social, private, and economic relationships—or even to sit next to—individuals who do not share their self-defined moral convictions (Skitka et al., 2005, 2012; Zaal et al., 2015). Moral emotions, such as disgust, are similarly related to social intolerance and aversive feelings toward outgroups, such as religious minorities and gay men (Ben-Nun Bloom & Courtemanche, 2015; Kiss et al., 2020). There is more limited evidence for the effect of self-reported moral conviction in predicting political intolerance, defined as support for depriving individuals holding the opposing view of civil and political rights; Skitka et al. (2012) found evidence for such intolerance in China, but not the United States. Another study, using both sentimental and domain-theory indicators of morality, reported that moral emotions but not perceived harm decreased political tolerance, but this effect was not mediated by self-reported moral conviction (Ben-Nun Bloom, 2010). Both induced disgust and disgust sensitivity were found related to support for restrictions on LGBTQ, such as bathroom restrictions for transgenders, with harm assessments showing a weaker predictive power (Vanaman & Chapman, 2020; also

see Kiss et al., 2020). Those findings imply that moral emotions translate more easily into intolerance than moral reasoning.

All of these findings point to a link between morality and ingroup favoritism, where the ingroup may be organic (i.e., based on ethnicity, religion, or partisanship) or defined by adherence to a specific set of moral values. This link has both an evolutionary (DeScioli & Kurzban, 2013; Tooby & Cosmides, 2010) and neurological (Berns et al., 2012) basis. An individual who expresses a moral judgment signals to fellow group members which side she supports in a conflict. This information, in turn, enables a third party to express solidarity and punish violators of a norm. Thus, expressing moral judgments reduces the price of uncertainty in conflict and increases coordination within the group (DeScioli & Kurzban, 2013). The same argument applies to the evolution of religion as a mechanism for regulating social interaction and enforcing norms (Norenzayan, 2013), which explains why morality and religiosity are both associated with an increased tendency to punish “sinners.”

Indeed, we tend to recoil at compromise with others when values viewed as sacred are at stake (Ginges et al., 2007; Tetlock, 2003). For instance, Ryan (2017) showed that moral conviction leads to the rejection of material incentives and reduced support for compromise, with the effect of moral conviction being comparable to the effect of holding extreme attitudes. In studies based on bargaining games, individuals who perceived an issue in moral terms were found to engage in more aggressive bargaining behavior when their opponents were perceived as holding opposing views (Delton et al., 2020). Such hostile moralized stances and behaviors only amplify the distance between political camps (Garrett & Bankert, 2018). Finally, a moral mindset amplifies not only opposition to compromise, but also opposition to politicians who are perceived as compromisers, or as willing to conduct negotiations on moral matters (Clifford, 2019; Ryan, 2017, 2019).

Still, studies have examined ways in which the polarizing role of morality can be attenuated. For instance, it was found that political arguments framed to appeal to the moral values of one's political opponents have the potential of reducing the attitudinal gap and tension between the two sides (Feinberg & Willer, 2015). In a similar vein, acknowledging the recipient's moral values by designing a two-sided message was found to encourage openness to the counter-attitudinal message among people with a strong moral basis for their attitudes (Xu and Petty, 2021). Sadly, however, when asked to craft an argument to convince one's political opponents, participants' arguments are significantly more likely to reflect their own moral values, rather than the moral values of the target of the message (Feinberg & Willer, 2015).

5.4. Voter Evaluations of Politicians

When morality is employed as a key evaluative criterion for political objects, it will inevitably be used for the evaluation of politicians as well. Classic models of impression formation in the field of social psychology did not examine morality as a separate dimension of social judgment, but rather suggested competence (“perceived ability”) and warmth (“perceived intent”) as the universal dimensions of social judgment (Abele et al., 2008; Fiske et al., 2007), with warmth being the more important of the two (Cuddy et al., 2011). In these classic models, moral traits were treated as simply one facet of warmth (Wojciszke et al., 1998).

However, an emerging newer model suggests that it is in fact the moral facet of warmth that drives its primacy in interpersonal evaluations (Brambilla et al., 2011; Brambilla et al., 2013; Leach et al., 2007). Findings pointing to the primacy of morality in impression formation lead us to expect that morality will be foremost in political evaluations as well, and that moral transgressions will damage politicians' images and consequently their chances for (re)election. This expectation is bolstered by the fact that individuals are motivated to perceive themselves as moral (Aronson, 1992)—a self-image that would be threatened by voting for a morally transgressing politician.

Indeed, voters value morality in political candidates. Classic studies examining the structure of candidate evaluations uniformly identify morality—often termed integrity, and sometimes honesty or trustworthiness—as an evaluative criterion (Kinder, 1986; Markus, 1982; Miller et al., 1986). Unsurprisingly, voters prefer candidates who espouse moral values closer to their own (e.g., Clifford, 2018). In a similar manner, evaluations of political servants often derive from partisan stereotypes. A cross-nation study suggests that liberal politicians are perceived to be more moral, specifically caring, and compassionate, whereas conservative politicians are considered to be more competent and “tough” (Bittner, 2015), although these stereotypes are at least partly context-dependent.

Nonetheless, findings pointing to the primacy of morality in impression formation in the social psychological literature do not necessarily translate well to the political realm. The political psychology literature suggests that overall, competence, rather than morality, tends to govern evaluations of political candidates (Castelli et al., 2009; Elkayam-Shalem & Ben-Nun Bloom, 2022; Funk, 1996; Mondak, 1995). For instance, in one classic study (Funk, 1996), hypothetical candidates in the United States presented as competent following a scandal were more positively perceived than candidates presented as warm. This is likely because, unlike in other social interactions, voters' primary concern when evaluating political figures is whether their representatives can “bring home the bacon.” Thus, voters are willing to overlook moral transgressions in politicians perceived as highly competent. This result was replicated outside the United States (Elkayam-Shalem & Ben-Nun Bloom, 2022).

That morality may be an important, but not the single most important, evaluative criterion for politicians is supported by studies into the electoral consequences of moral misconduct. Ample studies have found a negative effect of exposure to information about scandals on voters' evaluations of politicians (e.g., Bhatti et al., 2013; Doherty et al., 2011; Maier, 2010). Still, empirical evidence supports the notion that while moral scandals in politicians may have a cost in reduced vote shares (Basinger, 2018), they do not necessarily end careers (Welch & Hibbing, 1997). Reactions to politicians' moral transgressions may be contingent on different factors. This include both the nature of the behavior (for instance, illegal vs. morally dubious yet legal behavior) and audience characteristics, such as a voter's moral identity and partisanship (Elkayam-Shalem & Ben-Nun Bloom, 2022; Mölders et al., 2017) or voter's gender (Eggers et al., 2018). For example, in the context of the Clinton-Lewinsky affair, voters who had previously supported Clinton were less confident about the impropriety of his behavior and viewed it as less relevant to his political performance compared to non-supporters (Fischle, 2000). Walter and Redlawsk (2019) also found that voters' responses to moral violations by politicians are conditioned by partisanship, displaying a motivated-reasoning pattern. Finally, female voters in the United Kingdom were found to be more likely than men to punish politicians for moral misconduct, particularly female politicians (Eggers et al., 2018).

A multidisciplinary body of work suggests that even where political figures find their images tarnished by moral transgressions, they can effectively improve their image by shifting voters' focus to any dimension undamaged by scandal, including competence, warmth, and even morality in undamaged moral foundations. For instance, scandal-hit politicians who had violated the moral foundation of fairness were able to improve their overall image as well as moral image using loyalty appeals (an undamaged moral subdimension), but not fairness appeals (a damaged moral subdimension) (Elkayam-Shalem & Ben-Nun Bloom, 2022). This stream of work shows that voters rely on a multi-dimensional model of moral image in appraising politicians, joining other studies that suggest that the moral dimension of character may itself be divided into subdimensions (Clifford, 2018; Elkayam-Shalem & Ben-Nun Bloom, 2022; Goodwin et al., 2015). This view of moral character as multidimensional, together with voters' tendency for partisan motivated reasoning on behalf of one's ingroup politician, may help explain how scandal-hit politicians can nonetheless not only be reelected but also evaluated by voters as moral.

6. MEASURING MORALITY

There are two main ways of quantifying individual-level morality in public opinion. The first is through top-down theory-driven measures. These define the contents of the moral domain according to a certain theoretical perspective—be it moral foundations, domain-theory criteria, harm, or sentiments—and directly test for individual-level variance in these contents. The second is through bottom-up measures, primarily moral conviction, which ask respondents whether something reflects their moral beliefs. Finally, a moral mindset is often experimentally manipulated rather than measured. The right-hand side of Table 18.1 refers the interested reader to key measures for each of the perspectives discussed in Section 2. Below I discuss the most commonly used top-down and bottom-up measures, and briefly discuss experimental morality induction.

6.1. The Moral Foundations Questionnaire (MFQ)

By far the most frequently used theory-driven measure is Graham et al.'s (2009) Moral Foundations Questionnaire (MFQ) (see Ellemers et al., 2019, for a content analysis of morality measures). The MFQ is a 32-item measure (MFQ30, Graham et al. 2009; also available in a shorter form, MFQ20) designed to measure each of the five moral foundations. It does so by explicitly asking respondents for their (1) judgments on the relevance of considerations related to each of the five foundations (three items per foundation), and (2) endorsement of foundation-related values (three items per foundation; two additional items test attention to the task).

Notwithstanding its innovation and enormous popularity among political psychologists, the MFQ has been widely criticized, particularly for its validity. The main criticisms stem from the fact that the MFQ is a particularly inclusive paradigm that may confound related concepts. First, it is often argued that some of the measures for the binding foundations capture authoritarian personality (RWA) traits and social dominance orientation (SDO) rather

than distinct moral concepts (Federico et al., 2013; Kugler et al., 2014; Milojev et al., 2014). RWA is in fact strongly and positively correlated with the binding foundations, and SDO is strongly and negatively correlated with the individualizing foundations. Indeed, some MFQ items are heavily inspired by these measures (e.g., “Respect for authority is something all children need to learn”). In addition to suggesting that the moral measure confounds personality, this criticism reduces the MFT model to bi-dimensional.

Other scholars have noted the overlap between the MFQ and the second-most-often-used measure of endorsement of abstract moral rules (according to Ellemers et al.’s 2019 review)—namely, Schwartz’s Value Survey (SVS) (Feldman, 2020; Graham et al., 2011; Sverdluk et al., 2012; Zapko-Willmes et al., 2021). Values are intimately related to morality, as both are used to evaluate and express worth.¹⁰ The 57-item SVS¹¹ asks respondents to rate the importance of each of ten motivationally distinct types of values as a life-guiding principle.¹² This arrangement reflects the fact that all values are positive in valence, yet their rankings differ vastly between individuals.

Notably, a recent paper co-authored by Shalom Schwartz used a twin family study and self- and informant ratings with multi-rater data to examine the structural and genetic links between the MFQ and SVS. They found that the two are distinct psychological constructs, but associated in important ways. Thus, they show “partial convergence across different rater perspectives and a substantial genetic overlap” for conservation (versus openness to change) values and the binding foundations, which may reflect a common latent worldview—potentially security motives, sensitivity to threat, and the “dangerous world” belief (Zapko-Willmes et al., 2021, p. 1). Self-transcendence (versus self-enhancement) and the individualizing foundations were found to be “structurally divergent, but genetically linked,” such that “the entire genetic variance in Individualizing foundations fully overlapped with the genetic variance in Self-transcendence, but not vice versa.” They suggest that this association potentially reflects variance in the tradeoff between the core tendencies toward accomplishment of individual life goals and the pursue of social harmony (Zapko-Willmes et al., 2021, p. 11).

Other concerns have also arisen about the validity of the MFQ. While there is evidence for the model’s higher-order binding versus individualizing elements, the full five-factor model is not necessarily validated cross-culturally (e.g., Iurino & Saucier, 2018) and in specific sub-groups within the United States (Davis et al., 2016). Further, contrary to MFT’s narrative, the five foundations structure may not be heritable, as it was not found to be stable over time (Smith et al., 2017). Relatedly, it is often claimed that MFT—which is admittedly inductive rather than a-priori—may not be well grounded in either neuroscience or any other such systematic theory, and may be unfalsifiable.

Finally, the MFQ (and many other morality measures, including the SVS) capture rankings of abstract moral views rather than application of morality to a particular political issue. This has advantages, as it makes the measures generalizable to all issues and allows them to tap into a psychological essence detached from particular details. Nonetheless, declared abstract values may not directly capture the complexity of concrete political scenarios. This is because, holding constant a person’s abstract belief in a certain moral foundation, its specific application to a political outcome depends on idiosyncratic “informational assumptions” (Ben-Nun Bloom, 2010, 2013; Turiel et al., 1991) that may vary between contexts—as “all is fair in love and war.” These assumptions reflect the intensity and target of harm, intentionality, and the group identity of the perpetrator and victim, as well

as the setting (e.g., Crimston et al., 2016; Watkins, 2020). Indeed, in certain cases the MFQ is unable to predict moral behaviors that can be predicted by more concrete contextualized measures, which capture the rich details of the moral dilemma. For instance, the abstract loyalty subscale of the MFQ did not predict variance in intent of whistleblowing, whereas more contextualized measures of loyalty capturing concerns that an individual has regarding a negative impact of whistleblowing on their organization and relationship with coworkers did systematically decrease the odds of blowing the whistle within an organization (see Weidman et al., 2020 vs. Dungan et al., 2019; Schein, 2020).

While MFT has so far almost exclusively been measured using the MFQ, other measures have been proposed. Most notably, the Moral Foundations Sacredness Scale (MFSS)¹³ presents three specific moral violations within each of the moral foundations (e.g., “Stick a pin into the palm of a child you do not know”), asking the respondent how much money they would take to commit this action. The scale ranges from “I’d do it for free” to “Never for any amount of money,” capturing the sacredness of the value. Thus, the MFSS has the advantage over the MFQ of capturing decisions in specific scenarios rather than rating abstract principles.

Other measures response to specific moral dumbfounding vignettes such as the secretive incest story, eating a dead pet dog, and other foundation-related scenarios (e.g., Clifford et al., 2015; Feinberg & Willer, 2015; Frimer et al., 2013). While such measures have the advantage of examining responses to specific dilemmas rather than rankings of abstract principles, their focus on peculiar taboo violations does not necessarily capture the often-subtle trade-offs characterizing moral appraisal in complex real-world political decisions.

6.2. Domain Theory and Harm Measures

The intrinsic notion of harm underlying moral transgressions in domain theory yields some important distinctions between moral principles and social conventions, as defined by domain theory’s formal characteristics, which specify that moral regularities are universal, authority-independent, and unalterable. Thus, the standard domain theory measure of categorization to the moral domain in political issues captures the non-arbitrary nature of moral rules, differentiating them from social–personal conventions. Other works measure perceived harm more directly, for instance by asking respondents how threatening, dangerous, and harmful a particular object is perceived to be (e.g., Schein et al., 2016). I focus here on the standard measure and its offshoots.

The standard measure of belonging to the moral domain was developed by Turiel et al. (1991). Participants are first presented with a brief scenario or statement and are asked to categorize it: “Is [this act] all right or not all right? Why or why not?” Answers may be negative, positive, or “depends.” Then, respondents are presented with six items tailored to their responses, of which three concern the respondent’s country (e.g., the United States) and three some (unnamed) other country or countries. These items probe respondents’ views as to the legal status of the act (whether the act should be legal or illegal, and why), the legal contingency of their initial response (would the person change their judgment if the act was legal/illegal), and contingency on common practice (would the person change their judgment if the act was/ was not a common practice). In these questions, participants

answering that a certain political practice is all right are asked about their response to a situation where it is generally unaccepted or legally prohibited, while participants viewing the practice as not all right are asked about a situation where it is commonly accepted or legally allowed. The measure then examines whether the respondent's initial judgment is indeed universal, authority-independent, and unalterable, or whether it is affected by circumstances (e.g., by whether the act is a common practice). In addition, respondents' justifications for each criterion judgment are content-analyzed to examine whether they pertain to welfare, justice, and rights (issues associated with the moral domain), or to matters associated with the conventional or private domain (for the full measure, see Turiel et al., 1991).

Other works have adjusted this measure to suit political behavior surveys and experiments, eliminating the open-ended justifications, changing the binary responses to categorical scales, and developing a scaling method (for example, see measures in Ben-Nun Bloom, 2013, 2014). Findings from such studies show that people may range widely in the extent to which they categorize particular issues as being in the moral domain. At one extreme, people may regard a given issue as strictly conventional. Individuals may see the issue as wholly context-dependent, with issue-related behavior judged right or wrong based on the norms and legalities in a specific environment. At the other extreme, an issue may be regarded as belonging strictly to the moral domain, with related acts judged as right or wrong independent of laws, norms, and common practice.

The standard domain theory measure and its offshoots have several important advantages. Specifically, they are driven by a deductive theory of morality, concern real political issues rather than stylized scenarios, and contextualize the scales by tailoring items to the level of the political object rather than asking about an abstract principle. Still, they yield a continuous rather than a binary categorization to the moral domain (which may require using arbitrary cut-offs), may be too restrictive in regarding as conventional certain emotional and intuitive responses (such as to dumbfounding taboo violations), and may be cumbersome to use in a public opinion poll.

6.3. Moral Conviction

The respondent-driven instrument used most frequently by political psychologists (though it is not listed in Ellemers et al.'s review of measures) is the two-item self-reported moral conviction measure (Skitka et al., 2005). It directly asks respondents the extent to which their judgment about a certain political practice is "a reflection of your core moral beliefs and convictions" and is "connected to your beliefs about fundamental right and wrong." As such, this measure does not carry theoretical assumptions about the nature of the moral domain, but rather taps whether a participant believes that their moral values, as the participant conceives them, apply to a specific object.

While parsimonious, contextualized, and flexible, this measure confounds actual differences in levels of moral appraisal with differences in how respondents conceptualize and delineate morality. Moreover, an important assumption of this measure is that people have access to their own cognition, and are able to extract and report information concerning whether or not they employ a moral lens when thinking about a particular political issue. However, there is much evidence that people are often incapable of reporting their

attitudes and experiences in a representative manner (e.g., Wilson et al., 1995; Wilson & Schooler, 1991).

Further, a self-reported conviction measure may be biased in predictable ways. First, it may measure knowledge that a certain political issue is related to morals in the general political discourse, whether or not one has actually employed these concepts in her own belief system (Ben-Nun Bloom, 2010, for some indication that the moral conviction measure is associated with political knowledge). This is because exposure to moral rhetoric increases the likelihood of connecting political issues with morality and of relying on moral considerations when discussing political positions (Kraft, 2018). Self-serving bias may play a role too, as people may assign moral drivers to the attitudes they find most indicative of their own self-concept.¹⁴ Finally, people may also systematically differ in their willingness to relate to their personal preferences as “values” or “moral principles” (vs., for instance, preferences or positions), for instance based on whether they see value in analytical thinking or as a reflection of social desirability bias.

6.4. Manipulating Morality

This section has so far reviewed measures of morality. However, a moral mindset can also be manipulated or induced in an experiment. The main advantage of experimental manipulation of morality is that it can show a *causal* effect (as opposed to a statistical correlation) of a moral state of mind (vs. control) on political appraisal.

Moral manipulation may involve priming (altering *what* information is presented, by adding a cue that brings morality to mind), framing (altering *how* the information is presented, by adding a moral narrative which moralizes the message), or both. For instance, an experiment examining the persuasiveness of a moral frame embedded in an anti-abortion message may introduce disgust framing by conveying the message in disgust-driven terms such as “abhorrent,” “gruesome,” and “so horrible” as to evoke “a shudder of revulsion.”¹⁵ In an experiment using disgust priming, participants may be asked to start by reading a seemingly unrelated disgust-inducing essay, for instance on food or practices that are repulsive to most Westerners, accompanied by vivid pictures. In both experiments, respondents can be randomly assigned to a disgust exposure condition or a control condition, and will then respond to questions about their abortion attitudes.

Note that while framing offers valuable insights into important real-world moralization techniques, it has a pitfall, in that it often alters the information presented about the political message in a way that may offer an alternative explanation for the effect of induced morality. Accordingly, moral framing experiments require careful pretesting to ensure that the different treatments do not significantly differ in important dimensions such as message strength, negative valence, or arousal. Priming, by contrast, can make morality more accessible without altering the message, by inducing either object-relevant (e.g., unconscious feelings of abortion-related disgust) or incidental (e.g., feelings of disgust unrelated to abortion) moral cues. This enables the researcher to compare respondents’ political judgments in the presence and absence of the induced moral cue, while holding constant the information about the political act appraised. Yet the effect of some of the imaginative sensory disgust primes employed in the literature (such as exposure to repulsive odors, tastes, and

sounds) may be weak or unstable and sometimes difficult to replicate (Ghelfi et al., 2020; Landy & Goodwin, 2015).

How exactly morality is induced depends on the experimenter's definition of morality—that is, whether morality is seen as wholly or partially emotion-laden, foundation-based, and so on—and on the micro-mechanisms hypothesized to underlie the specific outcome variable. Many experiments focusing on sentimentalism use techniques such as those described above, which link moral emotions, such as disgust or empathy, to a political message or scenario (but see Cameron et al., 2015; Landy & Goodwin, 2015). For researchers relying on other perspectives, thoughts of harm or moral foundations such as fairness or loyalty can be induced using vignettes containing harmful scenarios or moral violations, either incidental or content-related (e.g., Ben-Nun Bloom, 2014; Clifford et al., 2015; Dungan et al., 2019; Monroe et al., 2021). Messages can be framed using various types of moral language (e.g., Feinberg & Willer, 2012; Kidwell et al., 2013). Finally, while this chapter focuses on moral judgment and moral reasoning, a moral mindset can also be induced by presenting participants with reminders of moral character or moral conduct, such as an honor code or the Ten Commandments (e.g., Mazar et al., 2008; but see Verschuere et al., 2018).

7. CONCLUSIONS

Moral thinking is a uniquely human cognition. Computer scientists at the cutting edge of their field are hard at work applying deep-learning artificial-intelligence paradigms in an effort to teach computers how to make moral judgments—with only partial success at best (see Jiang et al., 2021). Yet this process, which even the most sophisticated machine-learning algorithm is unable to imitate to a satisfying level, is one of the simplest and least effortful for people to engage in. Unlike a computer, a person can often decide almost instantaneously that “helping your political candidate” is noble and “helping your political candidate spread misinformation about vaccines” is not. This chapter shows the immense progress made in the last decade in the study of morality and public opinion, suggesting that intuitive and emotional moral judgments have a considerable influence on political attitude formation and political behavior. As people can be easily informed by their readily available and easy-to-use inner moral compass, public opinion may still be coherent even in the absence of detailed political information. Thus, emotional and intuitive moral judgments may explain why individual-level political attitudes are reasonably predictable, and why public opinion is overall stable and intelligible (Page & Shapiro, 1992), despite the robust evidence that the public is “innocent of ideology” (Converse, 1964).

As I have reviewed in this chapter, progress in the field is tightly related to different conceptual and methodological paradigms of morality. While there is striking convergence in these perspective on the importance of morality in a host of political outcomes, their overall conclusions with regard to its effect on specific political outcomes are often governed by the concrete conceptualization used. Indeed, the fact that the various perspectives cannot be easily integrated may point to the complexity of human morality. It is thus fair to conclude that the various perspectives complement each other by capturing different elements of morality in public opinion, and that they may be suited to studying different research questions.

Moreover, results from studies in the field are highly sensitive both to measures of moral state of mind and to measures of moral-political outputs. For instance, a study using moral conviction measures found that emotion, but not harm, moralized people's attitudes toward political issues and candidates—for example, leading a person to view a political issue such as a health care reform in a moral light (Skitka et al., 2017). Conversely, using a similar measurement framework but looking at within-person change in moral conviction from time 1 to time 2, it was found that harm, but not emotion, drives an increase in attitude moralization over time (Wisneski et al., 2020). Yet, applying a different set of measures and manipulations of harm (drawn from domain theory) and moral emotions (including disgust), other studies have found that *both* emotions and harm can affect attitude moralization—that is, viewing a range of political issues in a moral light (Ben-Nun Bloom, 2013, 2014).

Future studies in the field should work toward improving the interconnections between theories and findings, first and foremost by triangulating the various operationalizations. Further, the nature of the measures and definitions used should be taken into consideration when comparing findings or choosing between different operationalizations for a certain research design. Operatively, the MFQ is vastly more inclusive in gathering the various concerns semantically relevant to morality, but its discriminant validity from related social issues is admittedly low and it is detached from particular political details. Moral conviction items capture what respondents report as falling within their moral domain as they perceive it, but these are idiosyncratically understood. Domain theory directly measures moralization of concrete political objects via the characteristics it sees as unique to the moral domain, but it may leave out more transient, less reasoned conceptions of morality. Sentimental measures, in turn, suffer the reverse limitations. The SVS cites ten motivationally distinct types of values, of which only some directly relate to motivations for moral conduct (particularly benevolence, universalism, and tradition). Finally, stage theory measures capture differences in how people think about moral dilemmas, but are purely focused on reasoning and rely on substantial normative assumptions.

Generally, contextualized approaches can be more useful in predicting concrete political attitudes and behaviors than abstract or stylized measures. This is because moral judgments are highly sensitive to the specific circumstances: questions like whether incest involves consenting adults, whether pornography excludes child pornography, and whether a medically elective abortion takes place during or after the first trimester are all essential considerations in appraising their morality. Contextualized measures refer to such details when examining perceived harm or sentiments, and are thus better able to predict consequent attitudes and behaviors¹⁶. The challenge of generalizability in the field transcends differences in conceptualization and operationalization. The lion's share of research is US-based or is otherwise based largely on WEIRD (white, educated, industrialized, rich, and democratic) samples. In addition, with the exception of certain inquiries (e.g., work on the ideological asymmetry of morality), most research findings are scattered, even anecdotal, and are often examined within a certain research group, measure, and setting. This is particularly worrisome as studies have shown that the effect of morality is sensitive to the particular political issue examined, the political and cultural context, and the time frame of the analysis (e.g., Wang & Inbar, 2020; Wheeler et al., 2019), and as sources of uncertainty are often not reported. It is thus advisable for future studies to cast a wide analytic net whenever possible, to potentially apply more than a single framework, to improve scientific reporting,

and to be careful when attempting to generalize not just from particular measures or experimental stimuli but also from one-shot, single-issue, single-context studies.

Next, taking a historical perspective, as the field moved from normative stage theories to the inclusive moral foundations theory, it saw an erosion in its sensitivity to the tension between moral evaluation (what is perceived as moral) and moral value (what is in fact right in a certain context). Applying moral psychology to study public opinion naturally focuses on individual-level perceptions of morality. Yet the fact that an opinion is perceived as moral does not make it moral: people can perceive as morally justified (or not perceive as morally wrong) even the most heinous of ideologies. Future studies can examine the link between moralization of political objects and moral conduct, moral character, and ethical policies. For instance, perceptions of morality based on empathy do not guarantee fair policies, as they systematically privilege certain agents—for example, children, animals, the visibly appealing, and a single victim over many (Decety, 2021). Policy making based on feelings of disgust, too, may systematically disadvantage certain groups, such as religious minorities and LGBTQ (Ben-Nun Bloom & Courtemanche, 2015; Vanaman & Chapman, 2020)—in a way that may bias public opinion and downstream policy. Arguments from within the foundations of loyalty and authority may lead to unethical behavior—such as protecting a corrupt ingroup member—that are less likely under the foundation of fairness.

Finally, the field has moved from viewing reasoned principles and conscious deliberation as the major sources of morality to stressing sentiments, intuitions, and self-reported convictions (but see integrative and dual process models of morality, e.g., Greene, 2013; Ben-Nun Bloom, 2013; 2014; Schein et al., 2016). Moral reasoning is currently often viewed as rare, and as a post hoc process designed to justify a preceding intuition. Still, moral arguments, not sentiments, can vary with time in response to changes in the information environment. For instance, it was not disgust at the taste or odor of smoking, but rather new knowledge about the harmful effects of passive exposure to cigarette smoke, that was responsible for the moralization of discourse on this topic. Moral reasoning is thus essential in understanding political changes both in individual-level attitudes and on a societal scale. I have argued in this chapter that one of the most important contributions of the new science of moral psychology to political science is to stress the power of simple moral intuitions as potent heuristics in politics, which may help explain the stability of public opinion. Yet, to be able to study both stability and change in public opinion, and to explain differences both cross-culturally and over time, it may be useful to let the pendulum swing back to the middle, where both reasoning and sentiments are examined.

NOTES

1. The Heinz dilemma is a measure of moral development designed by Kohlberg. In this story, a woman is near death, and there is one highly expensive and overpriced drug that doctors think might save her. After her husband, Heinz, is unable to either raise the needed sum or persuade the druggist to lower his price, he considers stealing it. Should he? Participants' reasoning was coded into one of six stages, using a standard list of answers.
2. The trolley problem, introduced by Foot (1967), presents a situation in which an out-of-control trolley will inevitably kill five people working on the track—unless a switch is

- pulled which will divert the trolley onto a side track, where it will hit and kill one person. Is it morally acceptable to pull the switch?
3. Apparently not (Ben-Nun Bloom, 2014).
 4. The personal domain concerns matters of personal preference, choice, and boundaries (privacy and control), distinguishing a particular individual from others. Issues in this domain pertain only to private aspects of an individual's autonomic life and thus are outside the realm of conventions and morals (Nucci, 2001).
 5. While domain (and stage) theorists traditionally acknowledge that people experience emotions when thinking about morality, and that emotions facilitate the learning process about harm assumptions, they argue that emotions are not necessary or sufficient for the moral/conventional distinction to emerge (see Smetana, 2006).
 6. We will return to Shweder et al. and their three moral domains in more detail below, when discussing Haidt's moral foundations theory.
 7. It should be noted that domain theory does not require zero cross-cultural variance. Rather, it suggests that different contexts may lend themselves to different informational assumptions (i.e., what one accurately or mistakenly believes to be true) regarding the harmfulness of events.
 8. It has been found that holding an attitude with moral conviction and viewing the attitude as reflecting one's values are intimately related (Philipp-Muller et al., 2020). Hence, in this section I draw on some of the literature on values in persuasion, under the assumption that morality may play a similar role.
 9. For more on the difference between moral framing and moral priming, see section 6.4.
 10. Having value or worth by itself is not a sufficient criterion for belonging to the moral domain. For example, handsomeness has value, but pertains to the domain of personal preferences. Schwartz's model refers to values as distinct motivational goals, not as measures of merit.
 11. The Portrait Values Questionnaire—PVQ—is a shorter 21-item version.
 12. The first axis contrasts openness to change—encompassing the values of autonomy (self-direction) and excitement (stimulation)—with conservation, which advocates for preservation of the status quo (tradition), norm compliance (conformity), and safety (security). The second axis contrasts self-enhancement—emphasizing the pursuit of self-interest by seeking to control people and resources (power) or by seeking success (achievement)—with self-transcendence, which emphasizes concern for the well-being of others (benevolence) and acceptance and tolerance (universalism) (Schwartz, 1992, 2016).
 13. As reflected in the scoring system of the SVS but not the MFQ, values are all positive in valence, yet their rankings may differ vastly. Accordingly, the MFSS models moral foundations as trade-offs between concerns (e.g., testing a person's willingness to violate a moral concern for monetary payment; Tetlock, 2003), which potentially better captures the richness of moral appraisals in complex political decisions.
 14. There is some evidence that self-reported moral convictions point to self-relevance of the issue, with attitude dimensions indicating self-relevance of the attitude—importance and certainty—being the best predictors of moral conviction within participants and over time (see Brandt et al., 2016).
 15. Terms borrowed from the court's discussion in *Stenberg v. Carhart*.
 16. Another factor to consider is whether motivated moral cognition is at play, and particularly whether an individual's moral self is threatened upon appraisal of the moral dilemma. In such cases, it may be important to consider examining ethical dissonance (Barkan, Ayal, & Ariely, 2015), moral coping strategies (Ben-Nun Bloom et al., 2019), or moral hypocrisy (O'Connor, Effron, & Lucas, 2020).

CHAPTER 19

THE POLITICAL PSYCHOLOGY OF GENDER

MONICA C. SCHNEIDER AND ANGELA L. BOS

1. GENDER/SEX IN POLITICAL PSYCHOLOGY: AN OVERVIEW

GENDER/SEX¹—“AN umbrella term for both gender (socialization) and sex (biology/evolution) . . . where gender and sex cannot be easily or at all disentangled” (van Anders, 2015, p. 1181)—affects the way people live with, work with, interact with, and perceive each other. Layered on top of the reproductive, chromosomal, genital, and hormonal differences between females and males (sex) and the socialization of masculine and feminine qualities (gender), cultures afford power and status to male bodies and men more than to female bodies and women. In politics, where seeking, gaining, and wielding power are core activities, women’s inferior status persists across time and country. Even as women have tried to assert themselves as actors in the political sphere, people cling to the familiar actions of gendered prejudice and oppression. Though women have made many gains in social, political, and economic capital, gender/sex perseveres to shape political life.

As we write this chapter, we take stock of gains and challenges for political psychologists to investigate and explain. We note that, despite many women around the world rising to hold political leadership roles, such as former Chancellor Merkel in Germany and Vice-President Harris in the United States, women’s representation, at all levels of political office, lags worldwide. We observe women organizing to challenge the power of and oppression by men through the #MeToo movement and the worldwide Women’s March—and how women of color in particular have demonstrated leadership in these efforts as well as in the #BlackLivesMatter protests of police violence. We recognize the intersectional dynamics whereby Black women, Indigenous women, women of color, disabled women, and transgender women often struggle within social movements to have their voices heard and to have their unique group interests met. Worldwide, we witness hostility toward women political leaders. We behold a new generation of young people who are more open to gay rights and transgender identities, but continue to privilege traditional sexual and gender identities.

Each of these observations prompts questions about the ongoing and changing relationship between gender/sex, power, and stereotypes with political behavior and attitudes.

After decades of research that focused on binary sex differences, researchers still seem to feel compelled to look for such differences, despite evidence suggesting significant overlap between females and males (Hyde, 2005; Sapiro, 2003). We argue that research must push forward from a traditional “add women and stir” (Beckwith, 2005, p. 128) approach. Political psychology is uniquely situated to differentiate sex (biology) from gender (the “psychological features frequently associated with these biological states”) (Deaux, 1985, p. 51) and to shift our focus from sex to gender and its many complexities, including its intersection with race and other identities (see Pérez & Vicuña, Chapter 25, this volume). Through this shift, research can best specify how people create their gendered selves, in part as a collective response to norms, institutions, and policies that are themselves gendered (Diekmann & Schmader, 2021), as well as the mechanisms through which gender affects behavior (Wood & Eagly, 2015).

This chapter reviews research to illustrate when political psychology provides particularly excellent insights regarding gender/sex and politics, especially when scholars carefully ground their work in psychological theories of gender. Wood and Eagly (2009, p. 111) warn readers to pay attention to the *principle of compatibility*: Measures of gender/sex will only predict behavior when researchers align the appropriate aspect of gender with the behavior of interest. To this end, we draw attention to studies that exemplify a tight relationship between theory, expectations, measures, and outcomes, and underscore the continued promise of political psychology lenses to studying how gender, as a social construction tied to power, influences how people understand and experience politics.

We provide a roadmap for new and advanced readers to extant theory and research from the psychology of gender and how it gives insight into the effects of gender/sex in the political domain. We begin in Section 2 by defining key terms and presenting core theories that explain how and why gender develops. We review commonly used measures and highlight the need for careful measurement. Subsequently, we present empirical studies focused on explaining and understanding the powerful ways that gender/sex affect the political experiences of citizens’ political attitudes and behavior (Section 3) and elite behavior (Section 4). In Section 5 we shift to understanding how gender/sex affects leader evaluations. We give an overview of psychological theories and empirical findings related to why and how people judge others based on their gender. We conclude with insights regarding promising next steps for the field.

2. A PSYCHOLOGICAL APPROACH TO GENDER/SEX

Psychology tells us about what gender is, theories of how and why gender develops, and how it is measured. We encourage researchers less familiar with the psychological literature to use this as an introductory guide to their journey to proper conceptualization of gender and better theorization of its effects. Our focus on gender over sex reflects our view that gender, not the biology of sex, is more likely to predict political variables of interest.

2.1. Defining Gender

Gender broadly refers to aspects of the self in relation to society typically associated with men (masculine) or women (feminine).² Tate et al. (2014) argue in favor of conceptualizing gender as a “bundle” of constructs, making it crucial for researchers to choose and properly define the appropriate aspect of gender relevant for their research. The bundle of gender constructs includes birth-assigned gender, current gender identity, gender roles and expectations, gender social presentation, and gender evaluations. Gender incorporates feeling a sense of collective identity with like-group members (Wood & Eagly, 2009, 2015) that precedes politicized identity or feelings that the political fate of one’s gender is linked (Conover, 1988; Gurin, 1985). Finally, gender not only includes individual-level cognitions about how people define and express themselves, but also characterizes how people view each other and interact within a gendered social structure and gendered institutions (Diekmann & Schmader, 2021; Wood & Eagly, 2012).³

Gender identity often falls neatly on a binary and matches birth-assigned sex, but variation between and among people warrants additional attention. While many people self-report gendered personality characteristics consistent with the gender that matches their sex, some people express a cross-sex-typed personality (high on a feminine or masculine dimension but not in the other), one that is androgynous (high on both feminine and masculine dimensions), or one that is undifferentiated (low on both feminine and masculine dimensions). Nonbinary people experience the two dimensions of gender simultaneously or even not at all (Hyde et al., 2019). For transgender people, their sense of their own gender identity differs from their biological, birth-assigned category and might also differ from how others label and assign gender to them (Tate et al., 2014). Moreover, the self-assignment of gendered personality traits demonstrates variability and nuance over time, situation, and the life course (Wood & Eagly, 2015). Such change might be particularly pronounced for people who are transgender, who often delay public expression or admission of their gender identity, due to strong social norms to match gender identity with birth-assigned sex (Tate et al., 2014).

2.2. Theories of Gender

Why does gender/sex emerge as the basis for many human behaviors and cognitions? We present several theories from psychology that explain gender. These theories are not mutually exclusive, nor are they without debate. We privilege social role theory as our preferred lens through which to best explain gender (Schneider & Bos, 2019)—that is, the adaptation of men and women into different social roles bears responsibility for gendered behaviors. Thus, we give an overview of social role theory before offering alternative explanations for the causes of gender: biology, evolutionary theory, power-based theories, and group-based explanations. We view promise in other theories as well, arguing that insight into gender can come from many different directions, provided that the researchers are explicit in identifying their theoretical bent.

2.2.1. *Social Role Theory*

Social role theory implicates a societal sex-based division of labor, stemming from the adoption of different roles by males and females because of their biological strengths, to

explain gender (Eagly et al., 2000; Wood & Eagly, 2012). Men's superior physical power facilitated their success at tasks involving manual labor and farming, which eventually led to their entrance into the paid labor force and allowed them to acquire resources and power (Wood & Eagly, 2002). Women's ability to bear children—and the pre- and post-natal physical limitations—meant that they spent more time in pre-industrial societies performing labor inside the home. Through occupying these roles, men and women developed the traits necessary for successful performance in them. For men, this meant adopting agentic traits (e.g., aggressive, ambitious) to assist their success as hunters, farmers, workers, and eventually, leaders, whereas women acquired the communal traits (e.g., empathetic, caring, kind) essential for caring for others. The tendency of men and women to exhibit agentic and communal traits and behaviors, respectively, results not from biological differences, but rather from learning the traits necessary to perform in their assigned roles and from social pressure to continue conforming to those roles (Eagly et al., 2000).

Conforming to gender roles means more than just adopting particular traits; part of the gender socialization process consists of teaching people to prefer goals consistent with the gender stereotypical dimensions of communion and agency (Diekmann et al., 2017; see Sears & Brown, Chapter 3, this volume). The powerful reinforcement of binary gender norms results in boys learning to prioritize goals related to agency (seeking power, achievement, and new experiences) while girls adopt goals related to communion (seeking working with or helping others) (Diekmann & Schmader, 2021). Over time, men and women's preferences for a subset of agentic goals related to achievement have converged, but women still have a stronger preference for communal goals and for rejecting power-related goals relative to men (Diekmann et al., 2017; Schneider et al., 2016).

In sum, social role theory suggests that gender is a social construct derived from an ongoing gendered division of labor; gender roles perpetuate themselves because gender norms encourage conformity to these roles. Many scholars have found links between social roles and political attitudes and behavior (see work reviewed by Diekmann & Schneider, 2010; Schneider & Bos, 2019).

2.2.2. *Biological Explanations*

A biological perspective suggests that divergence in male and female brains and hormones might explain behavioral differences; yet, recent studies challenge both the existence of these differences and, where they exist, their effects. Brain studies demonstrate more similarities than differences between the brain structure of men and women (Hyde et al., 2019; Joel et al., 2015). While people believe that the hormone testosterone bears responsibility for the masculine or aggressive behavior of men, a review of studies demonstrate similar testosterone levels in both men and women (Hyde et al., 2019). High testosterone links to competition and low testosterone to nurturance, constructs that are not synonymous with masculinity and femininity (van Anders, 2013). Crucially, even when scientists find sex-based brain differences (Ruigrok et al., 2014), they do not always find a clear relationship between those differences and behavioral sex dissimilarities (Wallentin, 2009).

A more likely theory of the biology of gender/sex is that social factors and behavior determine hormones and brain differences, rather than the other way around (Hyde et al., 2019; Wood & Eagly, 2010, 2012). For instance, levels of testosterone are not fixed by biological sex, but instead respond to social stimuli like a baby crying (van Anders, 2013). In

short, scientists find little evidence that the biology of sex directly correlates to gendered behaviors, making its use in political psychology tenuous.

2.2.3. *Evolutionary Theory*

Evolutionary theorists argue that human psychological mechanisms and behavior developed to promote survival and reproduction (Tooby & Cosmides, 2015; Bang Petersen, Chapter 7, this volume). Gender differences, in particular, result from men's and women's physical differences in combination with their responses to unique challenges throughout evolutionary history. The exertion that pregnancy and breastfeeding requires shapes how women behave; for example, women tend to be more selective in their choice of mate and seek men who have physical characteristics that make them fit for reproduction (Buss & Schmitt, 2011). Because men have a low cost to procreation, they adopt sexual strategies appropriate to achieving a variety of sexual partners in short-term relationships.

Sidanius and Pratto's (1999) theory of Social Dominance Orientation (SDO) posits that people have a tendency to want to maintain group hierarchies and establish dominance over outgroups; such desire for power is evolutionary-based and organizes societies across cultures. Women's careful decision-making in choosing an appropriate mate for child bearing and rearing means that men must compete to attract women. This competition encourages men to desire power and resources, to seek domination over other groups (particularly men of other groups), and to create and maintain the patriarchy in order to preserve women as a reproductive resource. Sidanius and Pratto (1999) have amassed considerable evidence to show that men score higher than women on SDO, underlying broader political gender differences.

2.2.4. *Power Structure*

Theories focusing on power seek to understand how a group's placement in the larger hierarchical system conditions the behavior and attitudes of dominant and subordinate group members (Craig & Phillips, Chapter 23, this volume). Men, who enjoy a high social status, behave like members of other dominant groups by acting to support the social hierarchy and solidify their place in it (Jost et al., 2004). Subordinate group members, including women, counterintuitively, also often uphold the system to make sense of their subordinate status. Although people vary in their motivation to justify and support the system, both men and women tend to privilege men and male-stereotypical traits and behaviors as superior to those of women (Correll & Ridgeway, 2003).

2.2.5. *Group Identity*

Humans develop emotional attachments to groups in order to feel a sense of belonging and distinctiveness from others, perhaps as an evolutionary adaptation to solve challenges related to survival (e.g., Brewer, 2007). The predisposition for group identity combined with the power of gender as an enduring social and political category (Diekmann & Schmader, 2021; Sapiro, 1981b) result in varied forms of gender identity. Gender identity includes the way people define themselves personally with respect to gender (Wood & Eagly, 2015), the

way that they attach to their gender group socially, and, most importantly, the way that they view their gender group as having political importance (e.g., Gurin, 1985). People might be particularly likely to adopt gender-based self-categorization when gender is salient and/or situationally relevant (Huddy, 2013).

Crucial for political psychologists, gender identity can evolve in political importance and be used to “consciously engage in a power struggle on behalf of the group” (Simon & Klandermans, 2001, pp. 323–324). According to this model, as women (or any group) perceive injustice to their group, women’s identification with other women as a politically important group emerges as a powerful predictor of collective action. The subjective group identification that women feel toward each other, combined with shared grievances that they attribute to a bad system, constitute a set of feminist beliefs (Gurin, 1985; Huddy, 2013; Simon & Klandermans, 2001), where feminist identity can be defined as “the politicized version of a female identity” (Huddy & Willmann, 2021, p. 6). The #MeToo movement provides an example of the politicization of gender identity.

Intersectional approaches to identity recognize how multiply constituted marginalized identities affect how people experience the world (Crenshaw, 1991). Other identities, such as race, ethnicity, sexuality, status, and ability (to name a few), are experienced in conjunction with gender/sex. Rogers et al. (2015) used a narrative approach to uncover that Black high school students reported the centrality of both race and gender to their identity, but that the importance of these identities changed over time to both “support and compete with each other” (2015, p. 419). Intersectional scholars have amassed considerable evidence in favor of understanding how multiple identities develop in tandem (e.g., Ghavami et al., 2016).

2.2.6. *Gender Socialization Theories*

Children’s early gender socialization is a process through which they internalize gender concepts and stereotypes (Liben et al., 2002). Numerous theories have emerged regarding gender socialization and how people, starting in childhood, are socialized to gendered expectations and roles. Here, we briefly describe the major theories including theories social learning, cognitive development, gender schemas, and cognitive learning—biological, psychoanalytic, and intersectional (see Stockard, 2006, for a review).

Based on Social Learning Theory, sex-typed behaviors develop due to (1) modeling where children develop sex-typed behaviors because they model the behavior of other males or females and (2) reinforcement from others when they conform to expectations of their sex group (and lack of reinforcement when they do not conform) (Maccoby, 1992). Based on social role theory, through observing men and women holding sex-differentiated roles (e.g., men in roles such as leaders who are agentic and women in caretaking roles who are communal), children infer that sex-differentiated traits are needed to succeed in those roles. In addition, news coverage, children’s literature, and popular culture convey gender-appropriate roles for girls and boys; together, these media encourage girls to adopt communal traits and goals and encourage boys to develop agentic traits and goals (Diekmann & Murnen, 2004).

Multiple theoretical traditions emphasize the cognitive dynamics of gender socialization. In cognitive developmental theory, which builds on the work of Jean Piaget, children develop stereotypic conceptions of gender from what they see and hear around them, and

demonstrate increasing flexibility and complexity in understanding gender roles as they age (Kohlberg, 1966) and the capability for complex thought increases. According to gender schemas and cognitive learning theories, gender schemas are complex, multi-dimensional cognitive schemas that people use to keep information related to gender categories organized (Levy & Fivush, 1993). Through observing their culture, children develop gender schema and acquire sex-defined characteristics (e.g., traits, behaviors, preferences) that align with gender (Bem, 1981). In this model, children's gender schemas become more elaborate as they develop understanding of gender roles and their gender identity.

Psychoanalytic theory offers an alternative way to explain how gender becomes embedded in personality structures very early in our development (Stockard, 2006). In this theory, a child tends to first adopt a feminine identification, based on their main relationship often being with a mother or a female caretaker; they then embark on a process of embracing or rejecting this identification. This theory holds that boys' development of gender identity is challenging because they must work to repress their feminine identification developed through this first relationship (Chodorow, 1989). A sociology-oriented version of psychoanalytic theory holds that children first learn their role as a child; as they loosen ties with their mother and their fathers become more involved, they begin to adopt roles related to their gender identity (Stockard & Johnson, 1979).

2.3. Measurement of Gender/Sex

Having presented theories of why gender emerges, we turn to measures of gender that cut across these theoretical traditions. Before we begin, we note that the considerable complexity in conceptualizing and measuring sex and gender warrants several important considerations. First, neither gender nor sex should be measured as binary concepts (Hyde et al., 2019). Second, gender/sex should be measured via self-report to avoid inaccurate interviewer assessments (Albaugh, 2021; Westbrook & Saperstein, 2015). Third, gender should be treated as dynamic rather than static (Westbrook & Saperstein, 2015). Fourth, gender and sex questions should occur at the end of the survey to avoid priming respondents to think differently about subsequent questions (Cassino & Besen-Cassino, 2021). Fifth, language, culture, race, and ethnicity need to inform creating gender measures and adapting English-language questions for different contexts. Finally, researchers should carefully consider whether sex or gender—as well as which aspect of gender—will best predict the behavior of interest. Aligning “the content of the behavioral measure to the content of the dispositional measure” at the same “level of generality” (Wood & Eagly, 2009, p. 111) will ensure the compatibility of the measures to best predict behavior. For example, identifying with the interests of women as a group might predict gender-based political activity better than, say, a measure of preferences in interpersonal relationships, though both are valid measures of aspects of gender identity.

2.3.1. Sex

Multiple questions about gender/sex allow researchers to separate sex from gender (Albaugh, 2021; Saperstein & Westbrook, 2021; Tate et al., 2013). An appropriate question

about sex would ask for birth-assigned sex—since researchers and participants often cannot access information about chromosomal or other biological measures—and would include “male,” “female,” and “intersex” as response options. Transgender identity could be inferred from determining if a follow-up measure of gender identity differs from birth-assigned sex. Alternatively, a separate question simply asking if the respondent is transgender or not might avoid triggering transgender respondents, some of whom take offense to a question asking birth assigned sex (Albaugh, 2021), though reliability may be lower for such questions (Saperstein & Westbrook, 2021).

Before choosing any measure of sex, researchers should consider whether such a measurement is necessary for the outcomes of interest. Asking birth-assigned sex may be more relevant in medical research or for scholars studying the biological underpinnings of gender/sex through measuring hormones, brain activity, or genetic variation (Tate et al., 2013). For scholars studying the outcomes typically of interest to most political scientists, birth-assigned sex, on its face, has less predictive validity than gender identity (Albaugh, 2021).

2.3.2. *Gender*

While gender encompasses a number of constructs, a broad measure asking respondents their “current gender identity” (e.g., Albaugh, 2021) captures how people label themselves in the moment, since gender identity might change over time (Saperstein & Westbrook, 2021; Tate et al., 2013). The appropriate binary terms for response options in such a question would be “man” and “woman,” since male and female refer to sex, not gender. To capture people who do not identify as either men or women, researchers might use open-ended options, which allow respondents to use their own language to describe their identity. A free response option, such as “another gender, please specify,” avoids othering respondents who fall outside the gender binary (Albaugh, 2021), though one concern about asking open-ended questions is getting nonsense or confused responses. While this can occur, making it harder to decipher results (Saperstein & Westbrook, 2021), researchers must balance this possibility in their specific population with the need to create reliable and valid questions for those who fall outside the binary. Using a straightforward question about gender with three options (man, woman, free-response) should satisfy the goals of most political psychology research, though researchers with unique populations may need to consider additional options.

2.3.3. *Personality Traits*

Personality trait measures complement categorical gender/sex questions (Albaugh, 2021) by allowing respondents flexibility to self-report as having gradations of masculine and feminine attributes as two separate dimensions (Saperstein & Westbrook, 2021) or even to describe themselves as high or low on both dimensions (Wood & Eagly, 2015). The two most common personality trait measures include the Bem Sex Role Inventory (BSRI) (Bem, 1974) and the Personal Attributes Questionnaire (PAQ) (Spence et al., 1974), which were developed from questionnaires about the stereotypical and desirable characteristics of men and women. For example, the BSRI measures a person’s gendered personality traits on feminine (e.g., affectionate, compassionate, gentle, warm), masculine (e.g., competitive, assertive,

dominant, independent), and neutral (e.g., adaptable, helpful, reliable) dimensions (Bem, 1974, 1981). Participants are characterized as masculine, feminine, androgynous, or non-typed based on their responses and the level of difference between the scales.

One criticism of the BSRI/PAQ is that the measures define masculinity and femininity on behalf of respondents and, more broadly, may lack construct validity (Gidengil & Stolle, 2021). Self-placement on a single bipolar scale (Bittner & Goodyear-Grant, 2017) or two bidimensional scales (Gidengil & Stolle, 2021) of how feminine and masculine the respondent feels allows respondents to define the meaning of masculinity and femininity more generally than specific personality traits. Bidimensional scales performed better in predicting issue positions for people with atypical gender identities (Gidengil & Stolle, 2021). Response options ranged from a 7-point scale to a 0–100 feeling thermometer (Albaugh, 2021; Bittner & Goodyear-Grant, 2017). Political psychologists have begun utilizing personality measures of gender to great effect in predicting public opinion and political behavior (e.g., McDermott, 2016).

2.3.4. *Roles and Goals*

A facet of gender for researchers to consider is the gendered roles that people occupy as well as how people vary in identifying certain roles and goals as having personal relevance. Social role theory suggests that roles powerfully affect behavior. The gender segregation in occupational roles and in household labor means that men primarily work in leadership roles and perform wage labor, whereas women primarily occupy roles involving helping and working with others and perform the majority of the household and child-rearing tasks. Notwithstanding this gender segregation, people who occupy the same role will behave similarly, regardless of gender (Eagly et al., 2000). For example, teachers of any gender/sex will be more likely to share the same goals, interests, and traits than are a teacher and a CEO who have the same gender/sex. Crucially, people vary in the extent to which they identify these roles as being central to the self; a role may have a greater effect on behavior when it is personally significant or involving (Diekmann & Schneider, 2010). Gender also manifests itself in the goals that people value, identifying that communal-related goals (such as helping others, serving humanity, and working with people) or agentic goals (such as seeking power, recognition, achievement, and success) are of personal importance (Diekmann et al., 2010). Motivation to pursue these goals underlies choices to approach or avoid certain behaviors and roles; for example, women, who tend to prefer communal goals and eschew agentic goals, opt out of science, technology, engineering and math (STEM) pursuits because they do not see them as avenues to achieving their preferred and valued outcomes (Diekmann et al., 2017).

As a measure of gender, researchers might ask about occupational and other social roles (e.g., parenthood) and how important gender-related roles and goals are to respondents personally on scales ranging from not at all important to extremely important (Diekmann et al., 2010). Political psychologists have already begun to understand how women's distaste for power-related goals negatively affect their ambition for elective office (Schneider et al., 2016) and how parenting roles of motherhood and fatherhood affect their opinions and participation (e.g., Sharrow et al., 2018).

2.3.5. *Group Identity*

There are several options for conceptualizing and measuring how people relate to their gender group. For some, gender might be a significant part of who they are, indicated by

how highly they place their gender on a list of characteristics describing themselves (Wood & Eagly, 2009, 2015) or how easily they implicitly connect themselves to gendered terms in an Implicit Association Test (IAT) (van Well et al., 2007). Scholars measure a general sense of group identity through asking closed-ended questions about the group's importance, pride in the group, feelings of commonality with the group, and general closeness with the group (for example, see Conover, 1984).

More relevant to political psychologists, however, are the ways that people identify with groups in political terms, or group consciousness. One measure of group consciousness draws from work studying Black political identity and measures linked fate, or whether or not respondents feel their individual outcomes depend upon what happens to their group (Dawson, 1994; Gay et al., 2016). Other aspects of group consciousness include awareness of shared grievances, blame for the system for causing disparities, and belief that collective action can solve group inequities (e.g., Gurin, 1985; Huddy & Willmann, 2021). As one feminist identity measure, the American National Election Studies (ANES) consistently includes a feeling thermometer toward feminists or the women's liberation movement from 0 to 100 where higher numbers indicate warmer evaluations (Huddy et al., 2000; Huddy & Willmann, 2021). The ANES occasionally includes additional feminist identity measures, such as applying the term feminist to the self and identification as a feminist, as well as measures of perceived gender discrimination and gender resentment (Huddy & Willmann, 2021). Measures of gender consciousness predict both political participation (e.g., Duncan & Stewart, 2007), such as in the #MeToo movement (Jenkins et al., 2021), as well as political attitudes and partisanship (Conover, 1988; Huddy & Willmann, 2021).

Because people's multiple group identities shape the lens through which they view the political world, gender group consciousness might conflict with or enhance feelings of linked fate with other groups. For example, while Gay and Tate (1998) found that Black women mainly viewed politics through a racial lens, feeling connected to their gender identity conditioned their response to certain Black male political figures, such as Clarence Thomas and O. J. Simpson. Similarly, Brown's (2014) work demonstrates how gender and race together shape the identity of Black women politicians.

There is very little consistency in measurement of group consciousness across studies, which is further complicated by attempts to measure gender consciousness separately from feminism. Compounding this problem, researchers use a wide variety of qualitative and quantitative methods (see Abdelal et al., 2009). While we regret that we do not end this section with a clear set of recommendations, we urge a renewed interest in measuring gender consciousness, linked fate, and feminist identity and linking these measures to political participation and political attitudes, particularly since scholars have not found consistency in the relationship between gender consciousness, specifically measured as linked fate, with political outcomes (Gay et al., 2016). We also advocate for considering gender consciousness in conjunction with consciousness related to other identities, particularly gender-adjacent identities like LGBTQ or other politically significant identities, such as race.

2.4. Conclusions and Future Directions

We urge scholars to proceed cautiously when using sex since the biology of sex is rarely theoretically motivated in political research. Instead, we encourage measuring gender as a "bundle" of constructs. There is no single aspect of gender/sex universally appropriate for all theory and research in political psychology. Thus, we shared general principles for best

conceptualizing gender/sex with examples of scholarship that has successfully employed the measures. We elaborate even further on more such studies in the next section, but we anticipate that the best work will be yet to come as scholars feel confident that they can branch out in their theorizing as to how different aspects of gender might apply in a political context. We recognize that some of the measurement recommendations may seem overly complex and burdensome, particularly to those accustomed to measuring gender/sex as a binary, but we anticipate that these new measures will not only improve validity and reliability, but will also inspire research into marginalized populations.

3. HOW GENDER/SEX AFFECTS POLITICAL ATTITUDES AND BEHAVIOR

To emphasize the utility and predictive power of strong theoretical conceptions of gender/sex for research in the political realm, we review select findings that draw on the psychological theories and measures of gender from the previous section. We start with how children are first introduced to the gendered aspects of politics via gendered political socialization. We move on to exploring the gendered dynamics of adult public opinion and citizens' engagement and participation in politics. This review underscores that the effects of gender on political behavior are complex and conditional. We conclude the section with major points gleaned from our review and some ideas for future directions in these research areas.

3.1. Gendered Political Socialization

Children are exposed to and learn about politics and its gendered nature from a young age. But while research on both political socialization and gender socialization are plentiful, the combined effects of the two processes have not often been examined. Recent efforts by scholars in Europe (e.g., van Deth et al., 2011) and in the United States (Bos et al., 2021; Bos et al., 2019) are paving the way to understand the ways that gendered political socialization sets the foundation for later gender gaps in politics such as gaps in attitudes, participation, vote choice, knowledge, and ambition. This subsection draws upon the theory of gender socialization laid out earlier to introduce concepts in and research on political socialization and highlights research that aims to connect gender and political socialization processes.

Beginning in childhood, political socialization is the lifelong process of learning about and developing a set of beliefs and values related to politics (Sapiro, 2004) through a wide range of agents of socialization including family, school, media, and peers. Of these, family is often cited as the most powerful agent of socialization (Filler & Jennings, 2015; Oxley, 2017). Children develop more complex understandings of politics with age (Carter & Teten, 2002; Oxley et al., 2020), exhibiting "consistent, structured political orientations" regarding knowledge about politics, ideas about good citizenship, and familiarity with political issues by the first year of primary school (van Deth et al., 2011, p. 147), and demonstrating the development interest in politics by ages 8–14 (Haug, 2017).

When these processes of gender socialization (described above) and political socialization occur together, they combine to create gendered political socialization (Bos et al., 2021), which leads to two results. First, children learn that political leaders are predominantly men, who are perceived to engage in power-seeking behaviors more than cooperative and collaborative ones (Schneider et al., 2016), and that media (Lay et al., 2021) and school curricula (Cassese et al., 2014) emphasize the contributions of men in politics and more often highlight male stereotypical traits of political leaders. Based on these messages, when asked to draw a political leader, the vast majority of boys and girls ages 6–12 draw a man. Second, as a result of gendered messages about politics, gender differences in political outlooks emerge in childhood and adolescence (Bos et al., 2021; Fridkin & Kenney, 2007). Elementary school girls increasingly report less interest in politics and political careers than boys (Bos et al., 2019), and by age 15 there is a substantial gender gap in political interest among British children (Fraile & Sánchez-Vitores, 2020).

While gendered political socialization indicates negative effects on girls' political engagement, several findings point to positive effects of messages and role models on adolescent girls. Viable, novel women candidates inspire political discussion among young women (Wolbrecht & Campbell, 2017). When media covered prominent women politicians, the resultant increase in families' political discussion led adolescent girls to report greater intentions to be politically active (Campbell & Wolbrecht, 2006). Observing protests for women's rights motivates support for gender equality and engagement in politics: cross-nationally, adolescents who are exposed to media coverage of women's movement protests report increased support for equal gender roles (Banaszak et al., 2021). And a survey of adolescents and parents after the 2016 US presidential election revealed that Democratic girls, particularly those who felt disillusioned with the political system and those who had a parent participate in protests, indicated more interest in engaging in political protest (Campbell & Wolbrecht, 2020).

3.2. Gender Gaps in Public Opinion and Partisanship

Previously documented gaps between men and women in their political attitudes and their voting behavior warrant explanations based in political psychology. For example, men are more likely than women to support the use of military force and women are more likely than men to support social welfare issues. In the United States, women typically vote Democrat and men vote Republican (see Lizotte, 2020, for a review; Ondercin, 2017). These gender patterns in partisanship hold cross-nationally with women being more likely than men to identify with liberal political parties (Inglehart & Norris, 2000), and in European elections, women are more likely to vote for left-leaning political parties (Immerzeel et al., 2015). In this section we discuss what we see as three promising streams of inquiry into gender differences in political attitudes, including studies that focus on better measures of gender, those that apply social role theory to understanding gender gaps, and those that examine power dimensions related to gender.

First, efforts to better conceptualize and measure gender are advancing our knowledge of attitude gaps. In a nationally representative sample in the United States, McDermott (2016) found that identifying with male- and female-typical personality traits predicted

party, ideology, and political attitudes more than sex alone. People with masculine personality traits or those who feel masculine were more likely to identify as Republicans and support conservatism, while those with feminine personality traits or those who feel feminine were more likely to support healthcare and government involvement, and identify as a Democrat and a liberal (Bittner & Goodyear-Grant, 2017; McDermott, 2016). Traditional attitudes and beliefs accompany those who are gender-conforming: a study in Sweden found men who identified with many masculine traits and women who identified with many feminine traits were more right, traditionalist, and nationalist than those who were less gender conforming, while sex only weakly predicted political attitudes (Solevid et al., 2021). And, men in the United States who reported their gender identity as “completely masculine” and for whom that identity was “extremely important” to their overall identity were much less likely to support COVID-19 mask requirements (Cassino & Besen-Cassino, 2020).

Second, social role theory is a useful lens through which to understand gender gaps in public opinion (see Schneider & Bos, 2019, for a review). Social role theorists argue that women will adopt a diffuse gender role, and embrace communality (kind, caring) over agency (independent, aggressive), making them more likely to support policies that relate to compassion and care for vulnerable groups like increased public funding for education and to caring for the elderly. Similarly, women’s attraction to egalitarian and pro-social values, including tolerance, equality, social justice, and securing the well-being of others, mediates the relationship between sex and political attitudes, including attitudes toward use of force, environmentalism, equal rights, and social welfare issues (Lizotte, 2020). In contrast, men’s increased support for increased military conflict and greater opposition to government assistance programs relates to their greater individualism and aggression (e.g., Huddy et al., 2008).

Finally, using power as a theoretical lens to understand gender reveals how men’s greater power and status affects political attitudes. Men’s socialization to support the status quo from which they benefit contributes to their opposition toward redistributive policies (Bullock & Reppond, 2017; Schmitt & Wirth, 2009). In their pivotal work around Social Dominance Orientation, which combines both power-related dynamics with evolutionary theory, Sidanius and Pratto (1999) found that men’s greater orientation toward dominating other groups predicted their opposition to welfare state policies; the finding that SDO mediated the relationship between sex and political attitudes held up using cross-national data. In contrast, women’s lower power status and their experiences with discrimination leads them to be more sympathetic to transgender rights and the rights of other minority groups (Becker & Jones, 2020).

Power dynamics further inform how race interacts with gender to affect policy attitudes and party affiliation. The benefits that White women receive from being a part of the white heteropatriarchy help explain why they have been consistent supporters of a Republican and conservative agenda (including that of Donald Trump), while bBlack women, Latinas, and Asian women have been more consistent supporters of social welfare policies, larger government, and candidates from the Democratic party (e.g., Strolovitch et al., 2017). In contrast to white women, women of color’s greater sensitivity to these power inequities may explain why they demonstrate higher support for Democratic candidates in the United States than other identity groups (Bejarano, 2014) and why, even compared to Black men, Black women indicate higher support of progressive gender role attitudes and policies (J. S. Carter et al., 2009).

3.3. Political Knowledge, Participation, and Ambition

Similar to attitudinal divides, men and women differ in their political knowledge, interest, and behaviors ranging from discussing politics to running for political office. There is a consistent gender gap in political knowledge (Dolan, 2011), where men score 20–35% higher than women on a traditional five-point political knowledge battery (McGlone et al., 2006). Men engage in all forms of political participation—except voting—at higher rates than women (Burns et al., 2001). The size of the gender gap for various political acts ranges from 7 (e.g., in making financial contributions to political campaigns) to 15 points (e.g., paying attention to national politics). There are persistent differences between men and women in political ambition, or the desire to run for office, where women report less political ambition than men (Lawless & Fox, 2010). Identifying the root causes using theories of gender give insight into these behaviors.

3.3.1. *Knowledge*

Consideration of the gendered socialization of girls and women away from masculinized institutions and pursuits helps explain women's depressed political interest and knowledge as effects of gender and not sex. Women may not pursue information about politics as often as men or even in the same way. As evidence of the importance of gender on these outcomes, identification with masculine traits positively predicted political knowledge scores more than sex alone (McDermott, 2016). Women's scores on knowledge items equal or outperform men when the questions focused on topics more relevant to women's interests, such as government services or programs (Stolle & Gidengil, 2010) or women's representation at the national level (Dolan, 2011). Women experience larger knowledge gains from learning during political campaigns than men, which significantly reduces sex gaps in knowledge (Ondercin et al., 2011), and exposure to information can reduce or eliminate knowledge gaps (Jerit & Barabas, 2017). In short, socialization of women to be less interested in politics as well as to be only interested in certain areas of politics explains gaps in knowledge.

Interestingly, closer investigation into why men seem to have greater political knowledge reveals that the gap reflects differences in men and women's confidence in how they approach the survey. Approximately half of the gender gap is attributed to men being more likely to guess and their willingness to take risks on surveys in the United States (McGlone et al., 2006; Mondak & Anderson, 2004) and cross-nationally (Fortin-Rittberger, 2020). Discouraging "don't know" responses reduces women's uncertainty and reduces the gap (Mondak & Anderson, 2004). Stereotype threat, an effect by which reminding groups about negative group stereotypes depresses their performance on tasks and tests, applies here: when women college students were reminded of their group's stereotypical deficiencies in politics, they scored lower than men students (McGlone et al., 2006). Men's higher status teaches them to exhibit confidence and agency, whereas women's lower status leads them to internalize the stereotype that they are not equipped for politics; such power differences as the result of socialization help us think about these differences, in part, as artifacts of measurement.

3.3.2. *Political Participation*

To account for gender divides in a wide range of political participation, separating sex from gender-as-personality again proves to be effective. As part of her book on the

value of using female- and male-typical personality traits in the BSRI, regardless of sex, McDermott (2016) found a relationship between gendered personality and political engagement (including on items such as discussing politics and paying attention to political news). The findings demonstrate that masculinity motivates engagement in politics because it is a masculine domain: citizens with higher levels of masculinity are more likely to be politically engaged, whereas those reporting higher femininity are not (McDermott, 2016).

As with political knowledge, understanding the power dynamics with respect to gender can explain how women's lower status in the hierarchy depresses their participation in political life. The everyday experiences of women that objectify them (such as interpersonal encounters that focus on women's bodies, sexualized imagery of women in the media) reinforce women's inferior status and compliance with traditional gender roles. In experimental work, Calogero shows that such experiences discourage political activity and ultimately reduce women's likelihood of political participation and gender-based activism by increasing their ideological support for the status quo (Calogero, 2013, 2017). Ironically, then, women's everyday experiences cause them to defend, rationalize, and bolster, rather than dismantle, the status quo (Jost & van der Toorn, 2012) as they "align their self-concept and pursuits with their (unequal) status in the gender social hierarchy" (Calogero, 2017, p. 99).

Conceptualizing gender in terms of group membership and identity also improves insight into political participation and activism (Huddy, 2013; Simon & Klandermans, 2001). Feminists and women who feel personally connected to political events were more likely to participate politically (Duncan, 1999; Duncan & Stewart, 2007). Moreover, women might be more likely to engage in politics through their social networks. Black women, for example, create more social capital and engage with community groups more than Black men or white women, which partially explains their participation (Farris & Holman, 2014). And disabled women, who are more likely to participate in community groups than disabled men, participate politically as a result (Schur, 2003).

3.3.3. *Ambition*

Explanations of political ambition that link the psychology and socialization of gendered roles to the masculinized domain of political life add particular value to understanding gender dynamics in political ambition. For example, earlier we reviewed a goal congruity theory of gender, which suggests that gender socialization affects the goals that people have and the roles that they pursue. Applying this theory to political ambition, Schneider et al. (2016) found that both men and women perceived political careers as a way to pursue agentic goals of power and recognition. However, the authors hypothesized that such perceptions would affect men and women differently: because women, relative to men, are socialized to avoid conflict and reject power-related goals (such as pursuing power and recognition), they should therefore avoid political roles. Across two observational studies, the authors found that interest in conflict, a male-typical trait, and interest in power-related goals mediated the relationship between gender/sex and political ambition. Similarly, in interviews with graduate students well positioned to pursue careers as public servants and elected officials, women more than men reported that political careers would not help them achieve their goals for effecting change (Shames, 2017).

Experimental and applied work further demonstrates the value in examining political ambition through the lens of gender roles and goals. Women's engagement in politics seems to increase when communal goals, such as helping people or working with others, are at stake or when power-related goals are de-emphasized. In an observational study, women elected to office described that they decided to run for office because close friends and family encouraged it (Carroll & Sanbonmatsu, 2013). An experimental study showed that the gender ambition gap was reduced when political careers were framed as affording the opportunity to meet communal—over power-related—goals (Schneider et al., 2016, figure 4). Comparing participants' responses before and after a campaign training for women revealed that, on average, participants decreased their estimates of how much time politicians spend on power-related goals; those who changed their minds about the content of a political career increased in positivity toward one (Schneider & Sweet-Cushman, 2020). Of course, not all interventions affect women uniformly or positively: framing women's political underrepresentation as a demand issue (i.e., citing the ways in which the political system limits women's political opportunities) boosted white and Asian women's political ambition but depressed Black women's ambition compared to when framing as a supply issue (i.e., citing aspects of women's lives that make them less likely to run or to devalue their qualifications) (Holman & Schneider, 2018). Latinas' ambition was unaffected by either frame.

Role models have proven to be influential in encouraging women to seek STEM careers (e.g., Clark et al., 2016), particularly when the role model is seen as similar, inspirational, and attainable. While some studies in politics have found broad effects of women role models (e.g., Campbell & Wolbrecht, 2006), other studies have found null results (e.g., Foos & Gilardi, 2020); thus, testing the psychological mechanisms through which such change might occur has been under-explored in the political realm. An observational study of women in one campaign program showed that having women role models as presenters in the training only enhanced ambition when the participant identified with the role model (Sweet-Cushman, 2019). Experimental manipulations of role model gender and framing of the goals of the political career did not directly affect ambition, but women respondents did feel an increased identification and similarity when the role model was a woman or when the role model highlighted communal aspects of the career (Schneider & Holman, 2020).

3.4. Conclusions and Future Directions

This section demonstrates that gender, not sex, contributes to differences between men and women on a wide range of political experiences that span a lifetime—from early socialization through to the choice to run for political office. Thinking about gender as a bundle of constructs proves effective: personality traits, goals and roles, and identity with women as a group affect political attitudes, participation in politics, and ambition to seek political office. Scholars should continue to broaden their application of different aspects of the gender bundle to political questions. For example, the effects of many roles, such as parenthood, remain under-explored. Quantitative and qualitative work on how people experience gender identity and its politicization might also provide insight into political phenomena.

This section has highlighted how carefully applying the different theories of gender from psychology can advance our understanding of politics. We demonstrated that the effects

of the socialization of gender, such that men are taught to embrace agentic traits and roles whereas women are taught to embrace communal traits and roles, are powerful and far-reaching across many phenomena. Yet, we also displayed how thinking of gender as a power relationship between men and women complements this socialization focus. Moreover, this body of work shows that gender is not a monolith: research that challenges essentialism by uncovering how intersectional identities combine with gender to affect attitudes and outcomes crucially move the field forward. While these contributions are apparent, it is also clear that the future direction of political psychology work needs to deepen focus on stronger theorizing, consistently incorporate better measures of gender, and to emphasize intersectional frameworks and methodologies to understand political gaps.

4. GENDERED BEHAVIOR OF POLITICAL LEADERS

The effects of gender on behavior do not end when men and women are elected to political office. Understanding the psychology of elite political actors represents a promising research direction. Here, we share evidence that demonstrates how gender conditions leader behavior in ways similar to citizen behavior: elites act consistently with their gender identity by taking positions on and prioritizing issues that relate to gender-related goals and that are consistent with their gendered personality traits. Gender also reveals itself through interpersonal interactions and how political leaders approach their work; elite behavior often mirrors gendered expectations and socialization. And, as with the mass public, the intersection of gender with other identities, including race, affect elite behavior. To demonstrate the insightful research on elite behavior, we review three important books that use innovative methods to push the field forward.

Through extensive interviews with women members of the US Congress, Dittmar et al. (2018) contribute to our understanding of how women legislators engage their gender identity. The women reported identifying not just as a legislator, but as a woman legislator. The women convey how they are connected to each other through shared experiences, such as sexual harassment and violence. They also report how the challenges of facing stereotypes during a campaign and entering a male-dominated space—and facing harassment within that space—bonds them to each other. Through this shared sense of gender identity, women legislators are keenly aware of how their presence is symbolically important in empowering women. They detail the substantive ways they have advocated for women through addressing pressing issues of importance to women, such as sexual assault and harassment. Their comments make a compelling case that the way they approach governing is both distinctive and necessary during a time of intense partisan polarization and gridlock. Specifically, they detail how women legislators are more bipartisan and cooperative, value policy and productivity over power, and offer unique perspectives that contribute to legislative debates. And finally, the interviews underscore how the perspectives women of color legislators are shaped by their intersectional identities, which often means that they diverge from white women legislators. In short, this valuable book provides persuasive evidence that many facets of gender identity affect how women approach the position of legislator.

Nadia Brown's (2014) book *Sisters in the Statehouse* provides an exemplary intersectional work examining how gender and race affect the attitudes and behaviors of Black women

state legislators in Maryland. Using narrative methodology and one-on-one interviews, Brown traces how Black women legislators' identities are formed by their race, gender, and class as well as their experiences with discrimination. Brown analyzes the complexity with which these identities shape views on public policy, explaining how sometimes the women converge on issues, but other times diverge in their policy positions. In one example, Brown found that legislators united to argue for an alternative to a business program that specified a proportion of contracts for either minority-owned businesses or women-owned businesses. By establishing only two alternatives, the program required Black women business owners to choose a category instead of presenting their intersectional identity. Black women legislators were able to speak from personal experience on other issues disproportionately affecting Black women, such as domestic violence legislation in Maryland (N. E. Brown, 2014) and discrimination based on hair style and texture in New Jersey (N. E. Brown & Lemi, 2021). Overall, Brown reveals the unique ways that these legislators view themselves as Black women and applies this understanding to their electoral and lawmaking behavior.

Karpowitz and Mendelberg (2014) contribute to the body of knowledge through experiments replicating conditions experienced by women lawmakers to show that women's voices are largely silenced in group deliberations and that group rules and patterns work to inhibit their contributions. By varying deliberation rules and the gender composition of the group, the authors found that women spoke less often than men, experienced more interruptions, and had less influence on the overall decision of how to allocate societal resources, particularly when they constituted a minority of voices and when they were working within an environment with majoritarian versus unanimous rules for decision-making. Consistent with women's political socialization, their greater silence was explained by women in the study reporting less confidence than men. Because women took account of minority perspectives, showed concern for inequality, and exhibited a less competitive deliberation style more often than men, the implications of silencing women were stark. The absence of women's voices matters both for the substance of the outcome as well as the way in which decisions are reached. Through this innovative design replicating conditions experienced by women lawmakers, this work provides insight into how context interacts with gender socialization to affect the law-making process.

4.1. Conclusions and Future Directions

This section underscores recent attempts to expand our understanding of how gender shapes the experiences and behaviors of political leaders, efforts we hope will continue. Because of the difficulty in obtaining quantitative data on, say, the personality traits of men and women legislators, researchers must be creative in their approach. Here, we present a few examples of researchers who have done just that: Dittmar (2015) and Brown's (2014) interviews reveal a lot about the many aspects of gender identity and its intersection with race to condition the thoughts, behaviors, and voting preferences of women lawmakers. Karpowitz and Mendelberg (2014) use the power of the experimental method to give insight into gendered effects. We expect that future work will build on these studies and expand upon ways to use gender as a bundle of constructs in predicting elite behavior.

5. HOW GENDER/SEX AFFECTS POLITICAL LEADER EVALUATIONS

Over the past several decades, political psychologists have sought to understand whether and how gender/sex influences the way the public evaluates men and women political leaders, asking: do gendered cognitions limit women's representation in politics by affecting voters' choices? This section describes psychological theories of how people use gender to form inferences which scholars then apply to comprehend whether, how, and why voters view men and women political leaders differently. We review extant findings that provide evidence of role congruity theory—which explains prejudice against women leaders by the discrepancy between expectations for women and desirable qualities in leaders. Our review underscores that the effect of gender varies based on factors that alter women's fit with the political role and individual differences in support for the gender hierarchy. We conclude with suggestions for future research.

5.1. Psychological Theories of Gendered Evaluations

5.1.1. *Gender Stereotypes*

Gender stereotypes are attributions made to individuals based on outward appearance of gender. They are descriptive (defining what men or women are like), prescriptive (defining what men or women ought to be like), and proscriptive (what men or women should not be like) (Eagly & Karau, 2002). Stereotypes occur both consciously and subconsciously (Greenwald & Banaji, 1995). Social role theory provides one explanation for gender stereotypes, arguing that they originate from gender roles. As described earlier, this theory posits that the roles women have held throughout history—care-taking and private-sphere roles—means that not only do they often develop communal traits to succeed in those roles, but also that people assume that they possess these traits. Likewise, since men have held leader and bread-winning roles, people conclude that men have agentic traits necessary for male-dominated roles (Eagly et al., 2000). Because people tend to endorse gender stereotypes and gender roles, they believe that women and men ought to behave in ways congruent with their gender role and ought not behave in ways incongruent with their gender. That is, women not only *are* kind and caring, but they *ought* to be, and they should *not* behave aggressively.

An alternative to social role theory's explanation for stereotype origins, the Stereotype Content Model (SCM) argues that two key dimensions of stereotypes stem not from roles, but from a group's potential for threat and power (Fiske, 2012; Fiske et al., 2002). A warmth dimension characterizes groups based on perceptions of competitiveness—groups that are not competitive have high warmth—while a competence dimension differentiates groups based on high or low status. People perceive women as a group to have low competitiveness and low status, and, therefore, they are seen as high in warmth and low in competence.

5.1.2. *Models of Stereotype Effects*

Classic stereotype models argue that negative group stereotypes produce prejudice, but only under certain conditions. Stereotype activation or making the stereotype “accessible in one's

mind” must occur prior to stereotype application or the “extent to which one uses a group stereotype to judge a member of a stereotyped group” (Kunda & Spencer, 2003, p. 522). And, while stereotypes are often activated automatically to affect judgments, individual variation in goals, motivation, and the availability of information can disrupt the process and serve to “individuate” a member of a stereotyped group from a group stereotype (Brewer, 1988; Fiske & Neuberg, 1990; Kunda & Thagard, 1996). A negative group stereotype, such as a negative racial stereotype, that has been activated and applied would cause prejudice against a target.

Eagly and Karau (2002) argue that this model of prejudice will not apply to gender discrimination for two main reasons: (1) because stereotypes about women are largely positive, and (2) because the classic model does not account for the variation in prejudice across social roles that women experience. How, then, do gender stereotypes relate to prejudice toward women politicians? Role congruity theory (RCT) extends social role theory to explain that prejudice results when a group member seeks a counter-stereotypic role that challenges their prescribed social roles. To apply this to politics, women political leaders experience prejudice because women’s prescribed communality is incongruent with the agentic expectations for leadership roles (Bos et al., 2017; Eagly & Karau, 2002; Koenig et al., 2011; Schneider & Bos, 2019). Because of the association of men and masculine traits with leadership roles, when women political leaders behave communally and in accordance with stereotypical prescriptions, they will not meet the agentic expectations of leadership; conversely, if women behave as leaders, they will be judged negatively for lacking the communal qualities deemed appropriate for women and acting in ways proscriptive for women (Heilman & Okimoto, 2007; Schneider et al., 2021). In short, RCT scholars argue that prejudice results both from perceptions of women and from how these perceptions deviate from the qualities necessary for the leadership role.

From the perspective of the Stereotype Content Model (SCM), women, who are in a low-status, high-warmth quadrant, will experience paternalistic prejudice accompanied by emotions of pity and sympathy. Such prejudice can be conceptualized as benevolent sexism, which is “a subjectively positive orientation of protection, idealization, and affection directed toward women” (Glick et al., 2000, p. 763). Women professionals and feminists, however, are stereotyped as competent based on their high status, but also seen as lacking warmth (Fiske, 2012; Fiske et al., 2002). SCM predicts that groups in the high-status, low-warmth quadrant will elicit negative emotions, such as envy and jealousy. Women politicians fall under this category and would therefore experience prejudice, particularly because people are motivated to defend the gender hierarchy and women leaders violate that hierarchy by eschewing the prescribed status of women (Rudman et al., 2012). Hostile sexism measures individual-level variation in anger toward women who are perceived to be challenging men’s power. Ambivalent sexism, comprised of both hostile and benevolent sexism, refers to a set of individual beliefs that reflect preferences for upholding existing power structures (Glick & Fiske, 1996) and serve “to justify women’s subordinate status to men” (Glick et al., 2000, p. 763).

5.2. Measures of Gendered Evaluations

Many scholars of political psychology have adopted and tested a classic model that stereotypes of women applied to women leaders will cause prejudice in vote decisions and have, therefore, developed explicit and implicit measures of stereotypes. We

give an overview of these measures here, highlighting the variability in how political psychologists operationalize stereotypes and the strengths and weaknesses in their choices. Measures of gender stereotypes also take the first step toward testing RCT since RCT suggests that stereotypes of women must differ from expectations of the leadership role. We also include alternative measures that try to address role congruity more directly and measures that address individual-level beliefs in upholding the gender power structure.

Gender stereotypes of candidates are often measured by asking respondents “how well each of the following adjectives describe him/her” and to report their response on a scale from “not well at all” to “very well.” For example, Huddy and Terklidsen (1993) measured the traits stereotypical of women, such as warm, gentle, sensitive, emotional, talkative, and cautious, as well as traits stereotypical of men, such as assertive, coarse, tough, stern, masculine, active, rational, self-confident, and aggressive. As an additional measure of gender stereotypes, the authors analyzed how participants viewed men and women candidates with regard to the political issues they could handle well, focusing on military (e.g., military or police crisis), compassion (e.g., the poor, childcare), and economic (e.g., budget deficit) issues.

Studies have been inconsistent with regard to which traits stereotypical of men and women (see Schneider & Bos, 2014, Table 1, p. 247) and issue competencies they utilize. Recent efforts use traditional “ground up” psychological methods to help identify the stereotypes of politicians and how this content varies by gender (Schneider & Bos, 2014) and partisanship (Schneider & Bos, 2016). This work concludes that women politicians constitute a stereotypical subtype of women and politicians, sharing little overlap in stereotype content with these larger groups (Schneider & Bos, 2014; Sweet-Cushman, 2021). Scholars might therefore measure stereotypes of women politicians, including both positive and negative items, rather than measuring stereotypes of women alone.

In using any of these stereotype measures, social desirability presents a challenge since people perceive it to be socially unacceptable to report that they hold stereotypes about groups. Even while stereotypes about women are not negative, people might feel hesitant to differentiate based on sex, given clear social cues toward gender equality. A variety of measurement and methodological strategies have been developed to address this issue. One strategy is to ask about not what the respondent thinks, but what the respondent thinks *others* think (Schneider & Bos, 2014). In comparing a common explicit measure of bias toward women leaders to one that offers respondents a way to “save face,” Setzler (2019) shows that explicit measures underestimate bias, particularly for people belonging to groups in favor of gender equity.

Implicit measures, list experiments, and other methods that alleviate social desirability have been used successfully to measure gender stereotypes in politics. One implicit option is to use semantic differential measures where a respondent places a candidate on scales ranging, for example, from hard to soft or weak to strong (Bauer, 2015, 2020a; Krupnikov & Bauer, 2014). The Implicit Association Test (IAT) is the most common implicit measure (Greenwald et al., 1998) where participants are exposed to stimuli from two stereotyped groups and two stereotypical concepts. IAT measures reaction time to linking stereotype concept to groups; for example, in one study, participants who had more difficulty in classifying a woman candidate as a leader were less likely to vote for a woman (Mo, 2015). In

this study, both explicit and implicit bias toward female candidates significantly predicted vote choice. Using a list experiment, Streb et al. (2008) showed that social desirability pressures people to hide their reluctance to support a woman for the role. In this study, 26% of respondents were upset about the idea of a woman president. Krupnikov et al. (2016) showed that when asking study participants about a sensitive subject related to gender and race, simply giving respondents a chance to explain their decisions lessened social desirability pressures.

Multiple measures reflect individual differences in how people view women vis-à-vis the traditional gender hierarchy as such views might affect support for women candidates. For example, hostile sexism is measured through a respondent's agreement with ideas such as "women seek power by gaining control over men," whereas benevolent sexism is gauged through agreement items such as "women should be cherished and protected by men." Another related measure includes modern sexism (including items like "over the past few years, the government and news media have been showing more concern about the treatment of women than is warranted by women's actual experiences").⁴ In an attempt to directly test RCT, Schneider, Bos, and DiFilippo (2021) measured both proscriptive gender stereotypes (how women ought not behave) and expectations of the ideal inhabitant of the political role to study the effects of the disparity between the two. Finally, a respondent's evaluations of feminists, a group strongly associated with egalitarian gender relations, reflect ideas about gender relations (Huddy et al., 2000).

5.3. Empirical Findings on Gendered Evaluations

Early research from political psychologists experimentally varied the gender of a target candidate, uncovering clear differences in how voters perceive an otherwise identical woman versus man candidate with regard to beliefs (more liberal), traits (possessing women-typical traits), and issue competencies (women-typical issues like childcare) (e.g., Huddy & Terkildsen, 1993; Sapiro, 1981a; see a comprehensive list of traits in Table 1 in Schneider & Bos, 2014). Connecting these stereotypes to vote choice, however, proved more difficult: many scholars, using different explicit and implicit stereotype measures, established a relationship between gender stereotypes and voters' preferences (Mo, 2015; Sanbonmatsu, 2002), though many observational studies (e.g., Darcy & Schramm, 1977; Dolan, 2014) and some experimental studies (e.g., Sapiro, 1981a; Schneider, 2014) found a much weaker relationship.

We draw on a RCT perspective, which, rather than predicting a direct effect of stereotypes on vote choice, generates a set of hypotheses about when and how stereotypes about women—together with expectations about the politician role—might affect evaluations. In this section, we highlight how extant findings on the effects of gender cognitions are consistent with this theory and show the nuanced effects of gender stereotypes based on a candidate's congruity with the political leader role. In particular, role congruity depends on the campaign context, gendered campaign strategies, a candidate's political party identification, and intersectional identities. Finally, we underscore how individual differences in support of the gender hierarchy affect leader evaluations.

5.3.1. *Tests of Role Congruity Theory*

A growing body of research directly tests the primary premise of role congruity theory (RCT): bias against women leaders stems from the incongruity between the communal stereotypes attributed to women and agentic expectations for leadership roles (Eagly & Carli, 2007; Eagly & Karau, 2002). For example, Schneider, Bos and DiFillipo (2021) measured both expectations of the leadership role and stereotypes of women to show that people who believed that certain traits are necessary for the leadership role, but who also believe that those same traits are ones women ought not portray, were significantly less likely to support a woman candidate. Women politicians faced an agentic penalty where voters punished them for violating their proscriptive gender role because the leader role demands dominant, agentic traits. The authors also found that the incongruity between women and leaders—and the resultant penalty—was stronger when the electoral context emphasized male stereotypic strengths (national security focus) as opposed to female stereotypic strengths (care for vulnerable populations). Voters in an experimental study in the United States similarly penalized female politicians—that is, they were less likely to vote for them—for seeking power and thus violating prescribed communal expectations for them as women (Okimoto & Brescoll, 2010). And an observational test of RCT found that when viewing debates, voters reacted positively to German Chancellor Angela Merkel relative to her male opponent when she demonstrated happiness, an emotion congruent with both her gender and leadership. Voters further reacted negatively when Merkel displayed anger, an emotion incongruent with her gender but congruent with leadership, whereas her male opponents had more leeway to express such an emotion without penalty (Boussalis et al., 2021).

Also drawing directly on RCT, studies show that information introduced throughout the campaign can activate stereotypes and highlight women candidates' incongruity with leader roles or their deviation from gender roles. Conjoint and vignette experiments in Tunisia tested the effects on voter support of candidates presenting political platforms that were either gender-congruent or leadership-congruent (Blackman & Jackson, 2021). Women candidates whose platforms reflected women's issues, highlighting their incongruity with the political leader role, were less preferred. A conjoint experiment in Japan showed that when women candidates deviated from gender-based expectations—in traits and issue competencies—voters never rewarded them and in some cases punished them (Ono & Yamada, 2020). Bauer (2015) found that support for a woman candidate was only weakened in an experimental condition when feminine stereotypes such as “nurturing” and “compassionate” were activated. Activating stereotypes visually produces similar effects (Ditonto & Mattes, 2018). For example, Bauer and Carpinella (2018) found that masculine visuals (images of soldiers and of people in a business meeting) decreased evaluations of a female candidate's competence and electability by highlighting her lack of fit with the political role.

In low information settings or in the absence of party affiliation cues (Bos, 2011), voters are more likely to rely on broader stereotypes of women's lack of fit with the political leader role whereas in information-rich settings, voters can utilize other heuristics and information for their decisions (Andersen & Ditonto, 2018). And, because voters perceive women candidates as incongruent with leadership roles, they hold women candidates to a higher qualification standards (Bauer, 2020b, 2020c) and seek to assess a woman candidate's fit

with the role in their information search; for example, one study found that participants looked for more information about a woman candidate's competence and about "compassion issues" than they did for a man candidate (Ditonto et al., 2014).

5.3.2. *Election Context Affects Role Congruity*

Electoral contexts can highlight a woman candidate's congruity or incongruity with the role she seeks; we feature studies that ably test this key conjecture from RCT. Incongruity for women is particularly salient during military, terrorism, or economic crises, because men are seen as better at handling those issues. Survey data illustrated that during times of security threat, the public prefers male Republican leaders most and Democratic women leaders least (Holman et al., 2016). An experiment showed that a candidate's experience matters in conjunction with gender and context: the negative effects of a masculine context were lessened for former Secretary of State Hillary Clinton, who had experience in national security, as compared to House Speaker Nancy Pelosi, who does not (Holman et al., 2017). On the male-stereotypical issue of the economy, reading about economic volatility versus stability led participants to devalue the female, but not the male, candidate (Lei & Bodenhausen, 2018).

While war, terrorism, and poor economic conditions underscore women politicians' incongruity with politics, other contexts can benefit women candidates by highlighting how women's stereotypical strengths can be congruent with the leadership role. For instance, contexts of corruption may increase women's fit with the desired political leader role due to women being stereotyped as ethical, honest, or trustworthy. Barnes and Beaulieu (2014) used a survey experiment to show how the presence of a woman candidate reduced voters' suspicion of election fraud. Certain elections underscore women's issues such as in the 1992 US elections, dubbed "the year of the woman." Here, the context focused on candidate sex and gender issues, thereby underscoring women candidates' "fit" with political leadership, and encouraged voting for women candidates (Dolan, 2001). A woman candidate can also be seen as an "agent of change," as opposed to men candidates, who are seen as leadership status quo; this stereotype was particularly important to support for women candidates in the context of system threat (Brown et al., 2011). More recently, as the world was overturned by the global COVID-19 pandemic, studies indicated that this context allowed women leaders to successfully draw on and leverage women's traditional private sphere roles in their lives as political leaders (Johnson & Williams, 2020).

5.3.3. *Gender Stereotypes in Campaigns*

Scholars have long held that the effects of stereotypes on women's candidacies and electoral success are attenuated due to their anticipation of, strategic choices related to, and successful minimization of voter stereotypes in their campaigns (Huddy & Capelos, 2002). Candidates consider voter stereotypes in their campaign strategies to navigate "gendered terrain," as advised by campaign consultants who believe and advise that female candidates are being judged on masculinity and femininity (Dittmar, 2015). The strategies considered include decisions such as whether to "run as a man" versus "run as a woman" (Bauer, 2015), whether they should "go negative" (Krupnikov & Bauer, 2014) or display emotion (Boussalis et al.,

2021), and whether they can successfully achieve stereotype trespassing (Bauer, 2019) or overturn voter stereotypes (Schneider, 2014) to better align themselves with voters' expectations of the political role. Women candidates must balance a need to present themselves as agentic to portray competence in the leadership role without violating prescriptions of their gender role.

Evidence suggests considerable nuance in how these strategies help or hurt women in the delicate balance of conforming to gender and leader roles. For example, an observational study of the 2016 Irish general election showed that women candidates gained from strategically conforming to caregiver expectations, but also emphasizing their occupational credentials so as to not limit them to a caregiving role (Kusche, 2019). Voters reacted negatively to women candidates "going negative" because they saw these women as violating strong prescriptive gender stereotypes and acting in a proscriptive way (Krupnikov & Bauer, 2014). Finally, while women and men candidates were both able to persuade voters to overturn stereotypical expectations through their rhetoric, men candidates with gender-incongruent rhetoric still did better overall because voters saw him as fitting better with many different aspects of the leader role (Schneider, 2014).

5.3.4. *Partisan and Gender Stereotypes*

Because party affiliation is a primary lens by which politicians are evaluated in American politics, this identity presents important intersections with a candidate's gender that can affect evaluations. Many scholars theorize that party simply matters so much that it erases the effects of gendered cognitions (e.g., Dolan, 2014). However, psychological theory suggests that voters might process these two stereotypes together; indeed, Schneider and Bos (2016) found evidence that party and gender had both main effects and interactive effects on trait and issue stereotypes. An examination of feminine stereotype activation showed that both feminine stereotypes and partisanship influence how female candidates are perceived (Bauer, 2018). Very little research to date has addressed directly how the combination of gender and party identity would affect role incongruity and prejudice. Future studies might also focus on whether members of the Republican and Democrat parties have disparate expectations of proscriptive and prescriptive behavior for men and women to further understand role incongruity and political party expectations. Of course, party expectations will vary by country as well.

5.3.5. *Intersectional Stereotyping*

Candidates seeking office hold important identities beyond gender, such as those related to race, parenthood, religion, and ethnicity. Testing RCT—or other theories of prejudice—becomes more complex when considering these other identities, upon which voters are likely to draw to form their impressions and make vote decisions. Leadership role stereotypes are not only tied to men (Koenig et al., 2011) but also have pro-white biases (Gündemir et al., 2014). Yet, to add to this complex picture, as with stereotypes of women, intersectional stereotypes are often positive and do not automatically lend themselves to prejudice. Political psychologists have made considerable progress in understanding how different identities intertwine with gender to form impressions; future research could focus

on testing additional identity combinations and continue to understanding their effects vis-à-vis psychological theories of prejudice such as RCT.

Stereotypes of women vary considerably by race and ethnicity (Rosette et al., 2016). Mounting research shows that Black women and Latina candidates are uniquely positioned to capitalize on positive aspects of both gender and ethnic/racial stereotypes to win office (Bejarano, 2014; N. E. Brown & Gershon, 2016). Stereotypes of Black women candidates combine the strengths of stereotypes based on both gender and race, such that voters see them as more compassionate than other combined identity politician groups (Carew, 2016) and as more capable to handle civil rights issues (Gordon & Miller, 2005). Voters give Black women more leeway to display dominance as compared to white women (Livingston et al., 2012), which can make them more congruent with political leader roles. Intersectional stereotypes for Latina candidates similarly combine their group stereotypes. Latinas are seen as more capable to handle stereotypically feminine issues (education, assisting the poor, reproductive health, and healthcare), and minority issues (racial discrimination and immigration) (Cargile, 2016). Together, these studies underscore how stereotype content and effects are more complicated to unpack for candidates with intersecting identities and for multiracial candidates (Lemi, 2020).

As another example, stereotypes based on a candidate's sexual orientation and gender identity also intersect with gender/sex to affect candidate evaluations. Consistent with RCT, voters punish lesbian female candidates more so than gay men in their evaluations (Bailey & Nawara, 2017) because these women violate their gender roles both by seeking office and by not conforming to traditional female heterosexual gender roles. Sexuality changes the effect of gender: gay men are viewed as less competent on masculine issues, while lesbian women are seen as more competent on masculine issues than heterosexual women candidates (Doan & Haider-Markel, 2010). Transgender candidates might experience additional layers of prejudice since respondents reported lower likelihood to vote for transgender candidates, who they saw as more liberal and less able to represent them (Jones & Brewer, 2019).

Finally, parenthood could produce consequential intersections with gender as voters evaluate candidates. Motherhood, in particular, is a role highly connected with feminine traits and could underscore a women candidate's incongruence with the political leader role. Yet, it is not mothers, but rather women without children, who face a penalty from voters when they seek public office (Deason et al., 2015). This is likely due to their violating prescriptive stereotype expectations for what a woman should do. Though they are not being penalized for being mothers, women candidates who use maternal campaign appeals do lose voter support (Deason, 2011).

5.3.6. *Prejudice Stemming from Individual Differences in Gender Hierarchy Support*

Prejudice toward women seeking political leadership roles can stem from individual differences among citizens in their underlying sexist views and their support for the gender hierarchy. Ambivalent sexism has been tied to affective responses to the 2016 campaigns in the United States, which affected mobilization rates (Valentino et al., 2018). Hostile sexism in particular has been shown to affect evaluations of candidates (Utych, 2021) and vote

choice (e.g., Schaffner, 2020). Cassese and Barnes (2019) show that white women, especially those with lower incomes and without a college degree, who reported greater endorsement of hostile sexism and weaker perceptions of systemic discrimination, were more likely to vote for Donald Trump in the 2016 US presidential election.

Similarly, modern sexism broadly influences how voters seek information about female candidates in a campaign—and negatively affects their evaluations of and support for female candidates (Ditonto, 2019). In this study, using a Dynamic Process Tracing Environment methodology, voters who scored high on modern sexism sought less information about women candidates, were less likely to vote for a woman candidate in general, were less likely to vote for a woman candidate even when she was the candidate most aligned with their preferences, and rated women candidates more negatively than their male counterparts. Tesler and Sears (2010) showed that modern sexism was a strong predictor of Hillary Clinton's (un)favorability ratings in her first run for president. In short, these individual-level measures of sexism, though they come from a tradition other than RCT, help explain voters' choices.

5.4. Conclusions and Future Directions

In this section, we privileged RCT as a promising theoretical framework to study how gender/sex affects evaluations of women political leaders. Examples of tests of this theory using a variety of different methods illustrate the value of a RCT approach to revealing the conditions under which voters penalize women politicians; that is, when the campaign context, campaign strategies, or the candidate's or other intersectional group stereotypes highlight women's incongruity with political leader roles. As with studying the effects of gender/sex on political behavior, we believe strongly in the need for work to draw carefully from theories of gendered cognitions and to generate more direct tests of the role congruity framework in particular.

We also call on researchers to think creatively about a variety of expanded dependent measures to examine. This is, in part, because Krook (2020) identifies the monumental, worldwide problem of violence against women in politics and suggests that future research should go beyond vote choice to explain other behaviors toward women leaders. Explaining the effects of gender/sex on evaluations of elected officials are equally important. For example, preliminary evidence suggests that as respondents' sexism increases, male legislators were more likely to be rewarded for being friendly, but female legislators do not enjoy the same advantage due to gender stereotypes and expectations regarding women's behavior (Costa, 2020). Explaining evaluations of women and men once they are in office can be equally consequential to understanding women's underrepresentation and prejudice against women in politics worldwide.

6. FINAL THOUGHTS

We cannot overstate the significance of gender in every aspect of people's lives. For decades, psychologists have studied the ways in which gender is a fundamental organizing construct

that frames people's entire trajectory. A child's gender/sex is declared at birth, setting the expectation for their behavior and personality. Children learn their own gender, how to detect gender in others, and how deviation from birth-assigned gender can be met with resistance. In addition, gender combines and interacts with other identities. As children mature into adults, gender narrows the roles that they choose, from their occupation to roles within their family. Gender pervasively conditions how others see them and how much power they are afforded in society because cultures and institutions create and perpetuate gendered power structures.

Thus, it is no surprise that gender is a lens through which people understand politics and that gender structures citizen participation in politics. To best understand these dynamics, we argue that gender/sex must be carefully theorized before being applied to political variables. How do different aspects of the gender bundle affect public opinion and political participation? Future scholars can build upon the exemplary work highlighted in this chapter to further our understanding. For example, scholars might dig deeper into gender identity to give insight into how people's relationship to their gender identity and their gender roles affects political attitudes and behaviors. Research has only scratched the surface of understanding how people experience gender in combination with other identities to shape political views. While we promoted social role theory as the best framework for understanding gender and its effects, we also recognize that theories of gender socialization, power, and identity may work in tandem to provide the best insight.

Particularly given the gender inequalities in the political system and the problem this presents for democracy, there is a pressing, worldwide need to expand representation for gender-based interests in politics. Electing more women to office—and understanding how gendered cognitions limit women's access to seeking political office—may be one way to achieve this goal. Political psychologists who study gender are well positioned to generate further insights regarding how gender stereotypes can affect not only the election of women and their ongoing support from voters once in office, but also the increase in violence directed against them. In this review, we promoted the use of role congruity theory to understand discrimination and prejudice toward women leaders. We encourage future work to add direct tests of RCT and other theories of gender stereotypes in order to better understand the conditions under which gender does and does not matter for cognitions and behaviors toward political leaders.

We began this chapter with many examples of gender-based phenomenon in search of explanation; indeed, there is no shortage of ways that gender clearly affects political life. We expect future scholarship in this area to continue to leverage political psychology theories and the field's myriad methodologies to provide new understandings that improve gender equality and political representation.

NOTES

1. We use the term gender/sex throughout when gender and sex cannot be differentiated. See also Hyde et al. (2019) for discussion of this term.
2. Many psychologists refer to the "meanings attached to men and women" (Wood & Eagly, 2015, p. 1) as masculine and feminine, respectively. Scholars also use different terms to describe these constructs: agency (self-assertion and competitiveness) and instrumentality

are other names for masculinity, while communion (warmth and concern with others) and expressiveness describe the meaning attached to women (Wood & Eagly, 2015). Scholars using these terms should also take note that the constructs can include desirable traits (e.g., warm for femininity, assertive for masculinity) and undesirable traits (e.g., domineering for masculinity, whiny for femininity) (for a review, see Bos, Madonia, & Schneider, 2018).

3. Sexual orientation or sexual attraction obviously relates to gender/sex, identity, and political outcomes. Addressing this topic thoroughly and with proper attention goes beyond the scope of this chapter, but we recommend resources that introduce a psychological treatment of sexual desires as related to both sex and gender, such as van Anders' Sexual Configuration Theory (2015).
4. A subset of ambivalent sexism and modern sexism items can be found in secondary data sources such as the American National Election Studies (ANES).

CHAPTER 20

AUTHORITARIANISM AND POLITICAL CONFLICT

STANLEY FELDMAN AND CHRISTOPHER WEBER

1. AUTHORITARIANISM AND ANTI-DEMOCRATIC ATTITUDES

SOCIAL scientists in the 1930s and 1940s observing the rise of the Nazi Party in Germany, the ascendancy of fascist leaders like Mussolini, and the horrors of the Holocaust struggled to develop a way of understanding why people would support fascist parties and leaders and the atrocities they engaged in. One of the major contributions that emerged from this search was the concept of the authoritarian personality. This work was driven primarily by a small group of influential researchers at the Institute for Social Research in Frankfurt, Germany (Jay 1996). Among these, “Frankfurt School” scholars—Erich Fromm (1941) and later Theodor Adorno, Else Frenkel-Brunswick, Daniel Levinson, and Nevitt Sanford (1950)—developed the first detailed empirical account of what authoritarianism is and how it operates. Soon thereafter, research on the political psychology of authoritarianism grew, generating an expansive literature that has made major contributions to our understanding of the origins of prejudice, intolerance, ethnocentrism, and support for right-wing parties and politicians.

Eight decades later, studies drawing on the construct of authoritarianism continue to focus on many of the same phenomena that motivated the original researchers even as new political and social concerns present themselves. With increased movements of people around the world, ethnocentrism and prejudice that were directed at national minorities in the 20th century now often appear as opposition to immigration and demands for border control. Those impulses along with the mobilization of nationalism have been a feature of the growth of right-wing populist causes and leaders around the world (Huddy, Chapter 21, this volume; Mudde & Kaltwasser, 2017; Norris & Inglehart, 2019). Examples include Britain’s exit from the European Union, Donald Trump’s ascendancy in the United States, the rise of the Jaroslaw Kaczynski and the Law and Justice Party (PiS) in Poland, Viktor Orban’s Fidesz Party in Hungary, Rodrigo Duterte in the Philippines, and Narendra Modi’s Hindu nationalism in India. Norris and Inglehart (2019) describe support for these parties and leaders

as *authoritarian populism*, thus highlighting the connections between many contemporary political movements and aspects of psychological authoritarianism. While the world has gone through much change over the better part of a century, many of the issues that led to the start of research on authoritarianism continue to be relevant to politics today.

There is an expansive literature on authoritarianism within the social sciences that allows us to answer important questions about the nature of authoritarianism. First, *what is authoritarianism?* Despite its apparent simplicity, research on authoritarianism has been roiled by debates regarding the breadth and depth of the construct—what it should and should not entail—as well as how best to operationalize the construct in social analysis. It may seem surprising, but after decades of research, questions persist concerning the conceptual status of authoritarianism. Is it intertwined with conservatism? Is it an aspect of personality? A set of social attitudes? An orientation toward authorities and rules? Second, *what are the origins of authoritarianism?* Empirical research has put forth both biological and environmental explanations, with some demonstrating that authoritarianism is partially explained by genetics and evolution; other studies highlight how it is affected by socialization and life experiences. Authoritarianism is also shaped by environmental factors: education, friendships and social networks, societal levels of threat, and personality. How strong is the evidence that these factors are causal influences on authoritarianism?

Many of these questions will be addressed in the first half of our review. In the second half, we will move toward a more thorough description of how authoritarianism intersects and interacts with politics. Our third question is: *what is the relationship between authoritarianism and political ideology?* In its original formulation, authoritarianism was directly linked to right-wing political preferences (for a lengthier discussion of political ideology see Federico & Malka, Chapter 17, this volume). This continues to be the understanding that dominates much of the literature. Among the fiercest critiques of authoritarianism research is that the focus on *right-wing authoritarianism* misses an important question: Are authoritarian tendencies found on the political left? For instance, both Stalinism and Maoism practiced an authoritarian form of communist ideology. Fourth, *how is authoritarianism best measured?* Many of the debates that persist vis a vis measurement reflect the simple fact that authoritarianism and conservative preferences—in practice—are correlated. Self-report measures of authoritarianism—agreement with a series of attitudinal statements—were introduced by Adorno et al. (1950) and continue to persist in similar form. But the items that measure authoritarianism also reflect aspects of political ideology and attitudes toward social and political groups. Should we be measuring authoritarianism with statements occasionally veering close to the outcomes we expect authoritarianism to predict?

Finally, we will discuss how authoritarianism becomes aligned with electoral processes. *What are the conditions under which authoritarianism becomes associated with policy preferences and vote choice?* For most of its history, research on authoritarianism focused on estimating simple, direct effects. However, subsequent work has shown that authoritarianism exerts an effect under particular conditions—that is, political and social factors will moderate the effects of authoritarianism, increasing or decreasing its role as the social and political environment changes. Likewise, in a polarized party landscape, such as the United States, we also observe that authoritarianism tends to operate through partisanship, suggesting a mediated role. Recent research has begun to examine more carefully the political effects of authoritarianism as well as the circumstances under which it becomes politically consequential.

Our goal in this chapter is to review the literature on authoritarianism with a careful focus on these core questions. We will show how a thorough reading of the authoritarian literature, with an eye toward these questions, attests to the richness of this construct, in both its breadth and depth. Authoritarianism provides important insights into key aspects of contemporary politics—from intergroup attitudes, to support for national security measures, to voting behavior. We will highlight what is and what is not yet known about the dynamics of authoritarianism, as well as why it is a particularly useful construct for understanding a variety of political outcomes.

2. BACK TO THE BEGINNING: A BRIEF HISTORY OF AUTHORITARIANISM RESEARCH

Authoritarianism has a storied history within the social sciences. It emerged as a construct central to political and social thought in the 1930s, due largely to the pioneering work of the *Frankfurt School of Critical Theory*—a group of researchers led by Max Horkheimer, Theodor Adorno, Herbert Marcuse, and Erich Fromm, who were affiliated with the Weimar-era Institute for Social Research in Frankfurt, Germany (Jay, 1973). The Frankfurt School's work extended Marx and Engels' theorizing that economies move through societal arrangements that advance or lessen economic and political inequality. The Frankfurt School was neo-Marxist, by expanding Marx and Engels' insight to better understand how human psychology intersects with social, political, and economic arrangements. The Frankfurt School was quite critical of the central planning found in Marxism-Leninism.

The concept of psychological alienation was central to the Frankfurt School. According to orthodox Marxism, capitalism unleashed widespread innovation and human advancement; at the same time laissez-faire capitalism of the mid- to late 19th century devalued work and separated the worker from any inherent satisfaction in their labor. In Marxist doctrine, *such alienation* is typically understood to serve as a catalyst for a proletarian revolution. Workers will unite, demanding alternative, more egalitarian economic and political arrangements. The Frankfurt School advanced an altogether different narrative regarding alienation. They argued that free individuals might—in certain circumstances—abandon their freedoms for the security offered in authoritarian governing arrangements. In traditional Marxism, capitalist-led alienation ushers in a communist revolution; to the Frankfurt School, alienation may promote democratic backsliding toward autocracy, as individuals place trust in autocratic leaders. For instance, in *Escape from Freedom*, Erich Fromm (1941) elaborates on authoritarian submission, as it “help[s] the individual to escape from the unbearable feeling of aloneness and powerlessness” (p. 150) with the goal “to get rid of the individual self, to lose oneself; in other words, to get rid of the burden of freedom” (p. 151).

In interwar Germany, *Frankfurt School* scholars were uniquely and tragically situated to witness their predictions come to fruition with the rise of National Socialism in their home country of Germany (Bottomore, 1983/2010). Fromm (1929/1984), for instance, collected detailed qualitative and quantitative interviews of working-class Germans, and elaborated on the psychological characteristics giving rise to autocracy:

The authoritarian attitude affirms, seeks out and enjoys the subjugation of men under a high external power, whether this power is the state or leader, natural law, the past or God. The strong and powerful are simply admired and loved for these qualities, the weak and helpless hated and despised. (Fromm, 1984, 209–210)

Yet, it was not until the publication of *The Authoritarian Personality (TAP)* by Theodor Adorno, Frenkel-Brunswik, Levinson, and Sanford (1950) that an exhaustive individual treatment of the “authoritarian syndrome” was presented (see Brown, 1965/2004; Jay 1973). Through survey analysis, in-depth interviews, and projection-based techniques, such as the Thematic Apperception Test, clinical interviews, and interviews with parents and children, Adorno and colleagues (1950) advanced the notion that authoritarianism can be understood as a constellation of attitudes and beliefs, revolving around *anti-Semitism, prejudice and ethnocentrism, fascistic tendencies, and political and economic conservatism*. At the heart of the authoritarian character is a preference for autocratic rule and an endorsement of anti-democratic attitudes. It is perhaps for this reason that Adorno and colleagues named their self-report measure of the authoritarian personality the *F-scale* (Fascism Scale). The F-scale consists of nine interrelated facets forming the psychological basis for the authoritarian personality, based on the Freudian psychodynamic theory popular at that time (Adorno et al. 1950, 248):

1. Conventionalism and adherence to middle-class values.
2. Submission to perceived-to-be-legitimate authority figures.
3. Aggression those who violate conventional values and norms.
4. Anti-intracception, or “opposition to the subjective, the imaginative, the tender minded.”
5. Superstition and classification of the world into rigid categories
6. A preoccupation with power and toughness.
7. A cynical, oftentimes destructive, worldview.
8. Projection through the belief that the world is a dangerous and threatening place.
9. An exaggerated concern with sexual goings-on.

The Authoritarian Personality represented the first large-scale empirical assessment of authoritarian tendencies. The F-scale was found to positively correlate with anti-Semitism, ethnocentrism, and conservatism. Yet, within a few years of publication, *TAP* was roundly criticized by eminent social scientists in Richard Christie’s and Marie Jahoda’s edited volume “Studies in the Scope and Method of The Authoritarian Personality” (1954) (see also, Brown, 1965/2004; Stone, 1980; Duckitt 2001; Hetherington & Weiler, 2009; Federico et al., 2022). The *Studies and Scope* critiques were both methodological and substantively focused. Scholars noted that *TAP* samples were not based in probabilistic sampling, coders for open-ended responses were not completely blind to the researchers’ intentions, and survey items in the F-scale were worded in the same direction, confounding authoritarianism with acquiescence bias.

Among the fiercest critiques—and one that persists—is whether authoritarianism is an exclusively right-wing phenomenon. While Adorno et al (1950) understood the “authoritarian syndrome” to align with political and economic conservatism, later scholars would underscore the similarities between *authoritarian-fascists* and *authoritarian-communists*.

In particular, the authoritarian tendencies that gave rise to fascism appear closely resemble the authoritarian tendencies found in the writings and actions of Mao Zedong, Joseph Stalin, and Vladimir Lenin, for instance. Evidence for and against the existence of left-wing authoritarianism has been advanced in the years since the publication of TAP. We will return to this issue later in this chapter.

Due in part to the substantive and methodological criticisms of TAP, research on authoritarianism slowed in the 1960s and 1970s. However, some significant contributions were made in these years. For example, Milton Rokeach (1960) introduced the concept of *dogmatism*, a construct reflecting the tendency to approach the social world with an open versus closed mind. *Dogmatism* advances elements that originated in *The Authoritarian Personality*, such as the notion that humans vary in their propensity to view the world in black-and-white terms. Dogmatism, however, was intended to be apolitical in nature thus addressing concerns about the exclusive right-wing focus of authoritarianism in TAP. Something similar is found in Eysenck's (1954) research, where social and political attitudes are arrayed on a *radicalism* versus *conservatism* dimension and *tender-* versus *tough-mindedness* dimension. Eysenck's tender- versus tough-minded dimension was located orthogonally to the radicalism-conservatism dimension, suggesting that tough-minded (authoritarian) attitudes can be found on the left and right.

3. BOB ALTEMEYER AND THE RENEWAL OF INTEREST IN AUTHORITARIANISM

Bob Altemeyer's (1981, 1988, 1996) pioneering work on *Right-Wing Authoritarianism* (RWA) prompted a resurgence of authoritarianism research in the social sciences (Duckitt 2001; Hetherington & Weiler, 2009; Federico, Feldman & Weber, 2022). Altemeyer simplified TAP by reducing the nine F-scale dimensions to three interrelated components: submission to authority, adherence to conventional social and moral standards, and aggression against those who violate traditional norms and convention (Altemeyer, 1981/1988/1996). Moreover, Altemeyer side-stepped concerns about the ideological tenor of the construct, acknowledging quite directly that his focus is on a right-leaning authoritarian's tendency to endorse traditionalism and conservative social arrangements.

Altemeyer's (1981/1988) RWA scale substantially simplified the measurement of authoritarianism by including attitudinal statements reflective of the three core components of right-wing authoritarianism that he identified. The scale also addressed measurement concerns surrounding the *F-scale*. In practice, the scale typically exhibits high levels of reliability, and the survey items are presented in both a *pro-* and a *con-* trait direction, minimizing the influence of acquiescence bias. Indeed, Altemeyer's apparent success in providing a methodologically justified measure is largely responsible for the resurgence of authoritarianism-based research in the late 20th century. The RWA measure is not free from criticism, however, and we will discuss issues related to the measurement of authoritarianism shortly.

Another important point of divergence was that Altemeyer conceived of authoritarianism as a *social attitude*, rather than a stable personality attribute (for a discussion of

personality and politics see Bakker, Chapter 2, this volume; see also, Duckitt, 2001). The three authoritarianism facets serve as “attitudinal clusters” and are largely the consequence of socially learned experiences. People high in authoritarianism, according to Altemeyer, tend to grow up in conservative, authoritarian families and their social networks are homogeneous, often devoid of social and ethnic diversity.

In Altemeyer’s conceptualization, authoritarianism is a learned attitude, rather than a stable personality characteristic. This distinction is important, as Altemeyer’s theorizing on RWA advanced a far more parsimonious understanding of the factors that produce authoritarian tendencies. In *TAP*, Freudian psychodynamic theory provided the explanatory framework for understanding authoritarianism. Yet, in the latter half of the twentieth century, Freudian theory largely fell out of favor in the social sciences in general and academic psychology more specifically. The waning influence of Freudian thought in the social sciences produced further uncertainty about the empirical value of authoritarianism in the social sciences. What are the causes of authoritarianism, if the entire theoretical apparatus used to understand its emergence are brought into question? Altemeyer’s (1981/1988/1996) work partially filled this void, showing little evidence to support the Freudian notion that cold and inconsistent childrearing are core components of authoritarianism. Instead, Altemeyer shifted the focus to how authoritarianism is learned through the social interactions young people have with friends and parents, and in schools.

Altemeyer (1988) also presented the findings from numerous studies he designed to explore what he termed “authoritarian aggression”—the willingness of those high in authoritarianism to support punitive measures advocated by government authorities targeting people and groups who deviate from social norms or are members of minority groups. These studies refined and extended some of the central claims in *TAP* that authoritarianism is a major predictor of political intolerance and prejudice.

Altemeyer’s extensive research program grew out of the development of his RWA scale. Ultimately, in his studies authoritarianism is what the RWA scale measures: conventionalism, submission, and aggression. Why do these three factors cohere among authoritarians? While Altemeyer’s social learning account sidesteps the absence of evidence for the Freudian theory in *TAP*, it is not clear that social learning, by itself, provides an adequate explanation for the phenomenon of authoritarianism. We thus turn to research that attempts to develop a deeper understanding of the nature and origins of authoritarianism.

4. THEORIES OF AUTHORITARIANISM: SOCIAL COHESION, VALUES, AND THREAT

John Duckitt’s (2001) Dual Process Model (DPM) of ideology and prejudice offers a conceptually rich approach to authoritarianism.¹ Duckitt’s model has its origins in studies that compared the effects of RWA and Social Dominance Orientation (SDO) (Pratto et al., 1994; Sidanius & Pratto, 2001; for a discussion of SDO see Craig & Phillips, Chapter 23, this volume) on generalized prejudice and intolerance (Altemeyer, 1998; McFarland 2010; McFarland & Adelson, 1996). These studies converged on several important conclusions that distinguished the two. First, RWA and SDO were only weakly correlated. Second,

in models including these scales, both substantially predicted measures of prejudice and intolerance.

Third, and perhaps most important, RWA and SDO have distinctive correlations with other psychological variables. For example, Altemeyer (1998) found that these two scales relate to different set of social values as measured by Schwartz's (1992; also see Feldman, 2003) model. RWA is most related to a dimension that has conservation values (security, conformity, and tradition) at one end and openness values (self-direction and stimulation) at the other. In contrast, SDO is correlated with a dimension that contrasts self-enhancement values (achievement, power, and hedonism) with self-transcendence values (universalism and benevolence). All of this suggests that RWA and SDO tap different constructs. Duckitt's dual process model attempts to develop a deeper understanding of the nature and origins of RWA and SDO in the context of a general model of prejudice and ideology. Given the focus of this chapter, we will discuss only that part of Duckitt's framework that relates to authoritarianism.

As did Altemeyer, Duckitt begins by conceptualizing authoritarianism—as measured by the RWA scale—as a set of social or ideological attitudes. For Altemeyer, the authoritarianism attitudes that are tapped by the RWA scale are simply expressions of the three components of right-wing authoritarianism. It is not clear what, if anything, is the glue that holds these three factors together. In contrast, Duckitt sees authoritarianism as a reflection of what he terms motivational goals or values: “high RWA expresses the value or motivational goal of establishing and maintaining collective or societal security, order, cohesion, and stability (as opposed to individual freedom, autonomy, and self-expression), which is made chronically salient for individuals by the socialized worldview belief that the social world is an inherently dangerous, unpredictable, and threatening (as opposed to safe, stable, and secure) place” (Duckitt & Sibley, 2010, p. 1867). In this framework, authoritarianism (RWA) is assumed to be a direct function of a worldview that portrays the world as dangerous and unpredictable and that is jointly shaped by personality factors and socialization. The effects of authoritarianism (prejudice, ethnocentrism, nationalism, right-wing ideology) are, in turn, a result of perceptions of threat to collective security—the motivational basis of authoritarianism.

The dangerous worldview at the heart of this model is assumed to be a function, in part, of a core personality dimension that reflects a desire for social conformity versus autonomy (Saucier 1994). In terms of the Big Five personality model, social conformity is a function of low openness to experience and, to a lesser extent, high conscientiousness. The desire for social conformity motivates people to protect the existing social order and, therefore, these individuals may be particularly sensitive to threats to that social order. Being chronically primed to view the world as threatening and unpredictable ultimately leads to the adoption of authoritarian beliefs. For Duckitt, personality has an indirect effect on authoritarianism through its influence on people's beliefs that the world is perceived as dangerous and threatening.

A significant feature of the conceptualization of authoritarianism in Duckitt's dual process model provides a more precise specification of the effects of authoritarianism on negative outgroup attitudes. Previous research comparing the influence of RWA and SDO on prejudice had typically employed measures of generalized prejudice—summary measures that combine antipathy toward several outgroups. But those groups may vary in important ways that alter the way in which such antipathies are influenced by authoritarianism and SDO.

Following up that idea, Duckitt and colleagues (Duckitt & Sibley, 2007; Asbrock et al., 2010; Asbrock et al., 2012) distinguished between groups that they labelled as dangerous (socially threatening but not subordinate), derogated (socially subordinate but not threatening), and dissident (those competing with the ingroup). Using cross-sectional and panel data, they found that RWA had significant effects on attitudes toward dissident and dangerous groups but no effect on derogated groups. This is consistent with the major thrust of the dual process model that authoritarianism should motivate prejudice against groups that are threats to the social order. Attitudes toward groups that do not pose such a threat—like derogated groups that are not threatening—are not related to authoritarianism (but are significantly predicted by SDO).

Other approaches to the conceptualization of authoritarianism share elements with Duckitt's model although they identify somewhat different attributes that form the core of authoritarianism. In Duckitt's model, RWA (what is measured by the RWA scale) is still considered to be the construct of authoritarianism. Dangerous worldview, personality, and socialization are assumed to be precursors to RWA. Is RWA really measuring authoritarianism or the attitudinal consequences of it? For example, Stenner (2005, 14) argues that "authoritarianism is an individual predisposition concerned with the appropriate balance between group authority and uniformity, on the one hand, and individual autonomy and diversity, on the other." This is similar to Norris and Inglehart (2019, 8) who define authoritarianism as "a cluster of values prioritizing collective security for the tribe at the expense of individual autonomy." They see collective security encompassing three components: security from instability and disorder, conformity to traditions, and obedience to leaders who protect the group. The second two components closely resemble Altemeyer's conventionalism and conformity factors.

Where does this concern with collective security come from? Feldman (2003; Feldman & Stenner, 1997; Stenner, 2005/2009) argues that the core of authoritarianism is a dimension that reflects the tradeoff between the values of social conformity and personal autonomy. Although it is likely that most people will at times view both values positively (see Gray & Durrheim 2013), there is an inherent tension between these values—the pursuit of social conformity is ultimately at odds with personal autonomy and vice versa. There will be situations in which individuals prioritize one of these values over the others. Therefore, these two values can be placed on a continuum, with one end anchored by social conformity, the other with personal autonomy. Those who place roughly equal weight on the two values would be located near the midpoint of the dimension. On the other hand, at the extremes are those who consistently favor the pursuit of one of these two values over. From this perspective, authoritarianism emerges from individuals who prioritize social conformity over personal autonomy. The value of social conformity in this conceptualization reflects the desire to maintain social cohesion.

In these conceptualizations, the dimension of social conformity versus personal autonomy is the primary factor used to identify one's authoritarian beliefs (or lack thereof). For Feldman (2003; Feldman & Stenner, 1997) and Stenner (2005/2009), the social and political attitudes characteristic of authoritarians—prejudice, intolerance, punitiveness—are behavioral consequences of the desire to maintain social conformity and cohesion. The attitudes captured by RWA-type measures are thus seen as *consequences* of authoritarian predispositions and not the construct itself. Social threat in these models plays a critical role: "People who value social conformity are predisposed to be intolerant but may not

be intolerant without the required threat, whether it is a particular group that is threatening or a perception that social cohesion is in danger more generally" (Feldman 2003, 52). From this perspective, high scores on RWA-type measures should be a function of the value placed on social conformity/cohesion in combination with high levels of social threat.

5. THREAT AND AUTHORITARIANISM

Throughout much of its history, authoritarianism research has examined simple, direct effects of authoritarianism measures on social and political attitudes. But why do we appear to see authoritarianism impacting political attitudes and behavior only in some places at some times? The responsiveness of authoritarianism to threat provides a mechanism that can account for over-time variation in the political effects of authoritarianism.

Researchers since Fromm (1941) have discussed and studied the relationship between threat and authoritarianism though the hypothesized causal mechanisms vary. Doty, Peterson, and Winter (1991; Peterson et al., 1993), extending earlier work by Sales (1973), examined how social threat, measured in terms of overall social and economic stability, contributed to increases in authoritarian behavior. In the United States, the period from 1978 to 1982 can be considered *high threat*; it was marked by economic uncertainty defined by high unemployment and inflation, an energy crisis, and the Iran-Hostage crisis. During these years, Doty and colleagues observe more authoritarian behavior relative to a *lower threat* period from 1982 to 1987—a period in which the White middle class in the United States enjoyed comparatively more economic security. Thus, a common way to view the threat and authoritarianism relationship is within a causal structure—salient threat motivates the adoption of authoritarian values (Duckitt, 2001); one *escapes from freedom* and sacrifices individuality because of a worldview in which the social world is seen as a dangerous and threatening place.

From a different perspective, threat plays a more interactive, dynamic role. It alters the manner and degree in which authoritarianism is expressed. The interaction between threat and authoritarianism has been the subject of much discussion and research (see Duckitt, 2013, and Feldman, 2013, for discussions of this). A major issue has been whether people high in authoritarianism are generally sensitive to a wide range of threats or are responsive only to certain types of threats. The conceptualizations just discussed predict that people high in authoritarianism should be uniquely responsive to threats to the social order and social cohesion while these same threats should have little or no effect on those low in authoritarianism. This prediction has been tested in several ways. Duckitt (2006) presented subjects with a range of different groups and followed that with a battery of questions to measure the extent to which the group was seen as a social threat or a competitive threat. The distinction between social and competitive threats is important here as competitive (economic) threats do not directly impact social cohesion. He found that effects of authoritarianism on negative responses to the groups were mediated by perceptions of social threat but not by competitiveness.

Other studies have directly tested the prediction that social threat should lead to the greatest outgroup animosity among those with authoritarian values. As a result, we tend to observe substantial variations in the simple marginal effect of authoritarianism on

prejudice and intolerance. Some studies have experimentally manipulated social threat. For example, Cohrs and Asbrock (2009) and Cohrs and Ibler (2009) examined the threat-authoritarianism interaction hypothesis by comparing the effects of authoritarianism on outgroup attitudes in conditions where threat from immigration was explicitly present or absent. Both studies found that threat increased hostility toward outgroups only among people high in authoritarianism. In addition, Cohrs and Asbrock (2009) found that outgroup hostility among authoritarians was higher when immigrants were portrayed as socially (culturally) threatening than when they were economically competitive.

Velez and Lavine (2017) tested the hypothesis that racial and ethnic diversity could act as threats to social cohesion among authoritarians. They examined the effects of authoritarianism among White Americans on racial prejudice, intolerance, and attitudes toward immigration as residential diversity varied. In areas with limited diversity, they found virtually no effect of authoritarianism. As residential diversity increased, however, the effect of authoritarianism on negative outgroup attitudes grew substantially larger, consistent with the idea that mere residential diversity functions as a threat. Similar dynamics of residential diversity were found in the Netherlands by Van Assche, Roets, Dhont, and Van Hiel (2014). Diversity was negatively related to attitudes toward immigrants only among those high in authoritarianism. Interestingly, they also found that diversity was related to *favorable* attitudes toward immigrants among low authoritarians. These studies show that ethnic and racial diversity is threatening to those high in authoritarianism and increases their hostility toward outgroups.

An alternative prediction concerning the interaction of threat and authoritarianism has been offered by Hetherington and Weiler (2009) and Hetherington and Suhay (2011). In their approach, individuals high in authoritarianism have habitually elevated perceptions of threat. As a result, social and political events should have little impact on them since additional threats provide decreasing marginal returns. Instead, Hetherington and colleagues argue, it is those *low* in authoritarianism who should respond to threatening events by supporting more aggressive government actions and policies that restrict civil liberties since they are otherwise unlikely to experience social threat. This leads to the prediction that an increase in threat should *reduce* the apparent effects of authoritarianism on political attitudes since it will make low authoritarians endorse the sort of security and punitive policies typical of high authoritarians. Hetherington and Suhay (2011) tested this experimentally by making the threat of terrorism salient. They then estimated the effects of authoritarianism on questions tapping a willingness to restrict civil liberties to protect against terrorism and use force against international threats. Consistent with their prediction, they found that it is those low in authoritarianism that are most affected by the experimental manipulation of terrorist threat (for a broader discussion on the psychological effects of terror threat see Snider et al., Chapter 14, this volume).

So, some studies find threat-induced xenophobia only among high authoritarians, and others only among lows. Several recent studies help to resolve this puzzle. Claassen and McLaren (2021) examined responses in 19 European countries in the 2014 European Social Survey in which some respondents were exposed to an experimental manipulation of “immigration threat”—by raising the specter of non-European immigration. This study design helps to sort out whether immigration threat increases opposition to immigration across levels of authoritarianism or just for those high or just those who are low. Although the magnitude of the immigration threat/authoritarianism interaction varied across countries

(from non-significant to substantively large), the evidence supported the high authoritarian activation prediction: the threat of non-European immigration increased opposition to immigration among those high in authoritarianism, but there was no support for an increase in opposition to immigration among those low in authoritarianism when threat was experimentally manipulated. Importantly, consistent with the findings of Cohrs and Asbrock (2009), Claassen and McLaren found that it was cultural threat from immigration that increased opposition among high authoritarians. Economic threat (from the skill level of immigrants) did not change levels of opposition to immigrants for people high or low in authoritarianism.

The divergence of the Hetherington and Suhay study, finding the strongest effects of threatened terrorism among low authoritarians, raises the possibility that the sorts of threat evoked by terrorism may moderate the effects of authoritarianism differently than the social conformity and diversity threats that many other studies have examined (see Feldman, 2013). Following this line of reasoning, Arikan (2022) designed a study to determine whether those high and low in authoritarianism respond to different types of threat. She did this by experimentally varying whether the threat to society or the personal threat of COVID-19 was made salient to respondents in several US samples. Although the results varied to some extent across the samples, support for tough policies to punish those not following COVID protocols increased among those high in authoritarianism in the societal threat condition while it increased among those low in the personal threat condition.

Stevens and Banducci (2022) use panel data in United Kingdom spanning two terrorist events to directly compare the effects of personal threat of terrorism and social (normative) threat on those high and low in authoritarianism. They measured normative threat as perceptions of ideological dissensus and personal threat as the identification of terrorism as the most important issue facing the nation. They broadly measured the effects of terrorist threat on support for right-wing leaders, opposition to immigration, and favoring greater military strength. They first found that both types of threat went up more among those high in authoritarianism than among low authoritarians. Importantly, they found effects of normative threat only among high authoritarians while personal threat influenced the dependent variables among low authoritarians.

Threat may not have a uniform effect across the authoritarian spectrum; instead, different types of threats resonate with authoritarians and non-authoritarians. While the majority of studies find support for the hypothesis that those high in authoritarianism will respond to threats to social cohesion and conformity, the Hetherington and Suhay (2011), Arikan (2022), and Stevens and Banducci (2022) studies suggest that low authoritarians are also sensitive to threat, in this case to existential or personal threat.

6. AUTHORITARIANISM AS A GROUP-LEVEL PHENOMENON

The focus on social cohesion and conformity in these models raises an issue that has not been extensively addressed in the authoritarianism literature: social cohesion is only meaningful with respect to one's social groups. For instance, consider an individual who values

social conformity over personal autonomy. Adhering to group norms depends upon identification with a specific group. So, if an individual is embedded in a relatively liberal social network, social cohesion might map onto a liberal worldview. On the other hand, if this person were embedded in a relatively conservative social network, social cohesion might map onto a conservative worldview. Consistent with this prediction, Gorska et al. 2021 found that the perception of positive and negative social norms toward minority groups moderated the effects of authoritarianism on outgroup animosity. And Roets, Au, and Van Hiel (2015) reported that in Singapore, a country that has made multiculturalism a strong social norm, authoritarianism is *positively* related to support for multiculturalism and attitudes toward outgroups, which is opposite what is almost always found in other research. Authoritarianism, as a general preference for social cohesion, is animated by our social identities and the norms of the groups we identify with.

While not fully appreciated, conceptualizations of authoritarianism that are based on social conformity and cohesion are inherently group-centric models. This perspective was first developed by John Duckitt (1989), in a paper that preceded his dual process model. Authoritarianism, as developed in this paper, involves a core tension reflecting the relationship between the group and individual: “At one extreme would be the belief that the purely personal needs, inclinations, and values of group members should be subordinated as completely as possible to the cohesion of the group and its requirements. At the other extreme would be the belief that the requirements of group cohesion should be subordinated as completely as possible to the autonomy and self-regulation of the individual member” (Duckitt, 1989, 71).

Stellmacher and Petzel (2005) built on Duckitt’s conceptualization by making explicit the specific group context within which authoritarian predispositions are activated. Their conceptualization, which they call *group authoritarianism*, predicts that those high in authoritarianism will react only to threats that involve their salient social identities. In this model, it is a threat to *ingroup identification* that produces responses typical of authoritarianism. Stellmacher and Petzel assume that people have—as Duckitt suggested—relatively stable beliefs about the relationship between the demands of group cohesion and the individual. What they call an “authoritarian reaction”—conformity to group norms, obedience to leaders, and intolerance of deviance—results when those with these generalized authoritarian predispositions experience threats to a strong ingroup identity.

Kreindler (2005) arrives at a similar conceptualization of authoritarianism starting from basic principles of social identity theory. She argues that “authoritarianism reflects a desire to uphold ingroup norms and to ensure that these norms are preserved. Authoritarianism is preceded by two necessary conditions: group identification (which engenders support for group norms) and the perception that existing norms are under threat (which engenders concern for their preservation)” (Kreindler, 2005, 97). She argues that social identity theory can account for the three core components of authoritarianism identified by Altemeyer: conventionalism (the adoption of group norms), authoritarian submission (respect for authorities who embody group values), and authoritarian aggression (punishing ingroup members who violate group norms) (for greater discussion of social identity theory see Hopkins, Chapter 9, Mason, Chapter 24, and Pérez & Vicuña, Chapter 25, this volume).

By a somewhat different route, Kessler and Cohrs (2008) arrived at a group-centric, *evolutionary* theory of authoritarianism. They suggest that authoritarianism could have been selected for—by evolutionary processes—as a mechanism to foster coordination and

cooperation in social groups. Common markers of group membership (conventionalism), ingroup loyalty (submission), and punishment of norm-violators (aggression) all help to maintain cohesion and cooperation among small groups (Bang Petersen, Chapter 7, this volume). Anthropology offers further insight into the importance of cohesive small groups. According to anthropologist Richard Lee (1979, Lee et al., 1999), several 20th-century hunter-gatherer societies were observed to be largely egalitarian in nature, where survival required human cooperation and coordination.

Drawing on Kessler and Cohrs (2008), it follows that a disposition toward conformity would have provided broad social value. In early human societies, authoritarianism might have provided the necessary glue to maintain security-providing, cohesive small groups. In small local communities, authoritarianism may have been selected to maintain intra- and inter-familial social bonds. Kessler and Cohrs (2008) suggest that authoritarianism—an individual's tendency to adhere to traditional group arrangements—increases sensitivity to local norms and customs, the desire to preserve traditional social arrangements, and the motivation to punish those who violate these arrangements. Authoritarianism may have been evolutionarily advantageous in maintaining small groups and punishing norm violation and may have emerged as a socio-cognitive mechanism to preserve local social arrangements. A certain number of individuals willing to prioritize the group over oneself will benefit the group. The social group offers security, thus enhancing survival and reproduction. Since humans invariably benefit from being in cooperative groups, Kessler and Cohrs argue that “reliance on conventions, submission to norm systems and the authorities embodying them, and aggression against norm violators has an adaptive value in increasing rates of cooperation in group and, in turn, enhancing group performance” (Kessler & Cohrs, 2008, 75). Groups that evolved with members who practiced authoritarian tendencies may therefore have been more likely to survive over time.

However, a problem with an evolutionary model such as this one, as the authors note, is that it is not easy to account for individual differences in a trait. If authoritarianism is adaptive, why are all people not highly authoritarian? Kessler and Cohrs speculate that overtime variations in environmental conditions could have altered the relative advantages of social conformity and autonomy. Some environments may have favored autonomy, others conformity. Those changing conditions could then have led to the maintenance of variation in authoritarianism in human populations.

Such group-based theories describe authoritarianism in non-ideological terms. A preference for social conformity over personal autonomy is animated by one's social groups. When cast in these terms, authoritarianism is not directly conflated with ideology. *The Authoritarian Personality* and *Right-Wing Authoritarianism* are concerned with authoritarians on the political right. While scholars have and continue to identify cases of authoritarianism on the left, in practice, the “left-wing-authoritarianism” has proven to be a somewhat elusive construct (Brown, 1965/2004; Eysenck, 1954; Rokeach, 1960)—a topic we shall explore later in this chapter. Whether there are left- and right-wing authoritarians (and what that entails) is a question that can be cast in different terms: how does the fundamental human tendency to submit to authority morph into a belief structure, a preference for a party, or ideologies that take on a particular ideological flavor?

As we have suggested, the way in which authoritarianism is *politically* and *ideologically expressed* depends upon one's group, who is considered a legitimate authority figure within that group, and that group's position relative to the dominant group—does one's group

hold a disproportionate share of social, political and/or economic power? Consider, for example, the work on authoritarianism in Russia shortly after the fall of the Soviet Union by McFarland and associates (McFarland et al., 1992/1993; McFarland et al., 1996). They found that RWA scores correlated *positively* with support for the Soviet Union and the value of equality and negatively with laissez-faire individualism. Among people for whom communism remained a core of their group identity, authoritarianism was associated with ideologically left-wing attitudes and values like equality and social justice.

In another example of the importance of group identity and social norms, authoritarianism has different consequences for White relative to Black Americans. Dusso (2017) examined the effects of authoritarianism among African-American voters in the 2012 American presidential election. Among White voters in the United States, there is a strong relationship between authoritarianism and support for Republican candidates (Hetherington & Weiler, 2009). Among Blacks, Dusso found that authoritarianism was *positively* associated with voting for Democratic candidate Barack Obama. This may be a function, in part, of the activation of group norms for authoritarians. Since Democratic identification is normative among African-Americans (White & Laird, 2020), the tendency for authoritarians to defend ingroup norms should lead to the observed positive association between authoritarianism and Democratic voting.

The group-centric model of authoritarianism puts forward questions that have not been adequately dealt with in research on authoritarianism: What is the “group” that people want to protect? An implicit assumption in much of the literature is that people are thinking about their national group—the nation. That is probably a reasonable assumption for members of national majority groups who see their group as prototypical of the nation (Devos & Banaji, 2005; Huddy, Chapter 21, this volume). What are the consequences of authoritarianism among minority group members? There is no reason why authoritarianism should not vary among minority group members to the same degree as majority group members (but see Henry, 2011, who argues that authoritarianism may be higher among members of minority groups). While majority and minority group members should experience some threats to social cohesion similarly, the growth and influence of minority groups and increasing social diversity should be threats to authoritarian members of majority groups but not minority groups. That should lead to divergences in the effects of authoritarianism across groups.

7. THE ORIGINS OF AUTHORITARIANISM

7.1. Evolutionary Approaches

Research suggests that authoritarian tendencies have both genetic and environmental foundations. As we just discussed, Kessler and Cohrs (2008) argue that authoritarianism may have emerged in human evolution to foster cooperation and preserve group structures. In evolutionary psychology, a literature has emerged around understanding how general-purpose cognitive modules emerged in human evolution. Human psychology includes an architecture informed by reactions to environmental conditions (Tooby & Cosmides, 1992). These adaptive cognitive modules are “content neutral”; the expression of these evolutionarily informed cognitions can be practiced and expressed in any number of ways (Barkow

et al., 1992; Bang Petersen, Chapter 7, this volume; Buss, 2008). Group submission, and a general concern with social cohesion, may have evolved as adaptive mechanisms to navigate the demands of group living.

A related literature on the so-called *moral emotions* addresses psychological structures oriented around authority and group cohesion (Buss, 2008; Haidt, 2012). Humans' cognitive apparatus consists of quick, automatic reactions to environmental stimuli. *Reaction* is more common than *reflection*. Humans typically navigate the "blooming, buzzing confusion" of everyday life on autopilot, relying on cognitive shortcuts, heuristics, and general rules-of-thumb (Jerit and Kam, Chapter 15, this volume). Emotions are an evolved part of humans' cognitive architecture, some of which are oriented to protect and preserve group arrangements. Evolved group-oriented emotions—such as shame, guilt, and embarrassment—are often prompted by actions that threaten social groups (Brader & Gadarian, Chapter 6, this volume). These group-centric emotions serve as "commitment devices" preserving social cohesion, order, and in some cases submission to authority (Buss, 2008, 402).

Haidt extends this reasoning to *moral foundations theory*, which also addresses the advantages that an evolved, group-centric orientation could provide, particularly applied to moral judgment (Ben-Nun Bloom, Chapter 18, this volume; Graham et al., 2009, 2012; Haidt & Joseph, 2004, 2007; Haidt et al., 2009; Haidt 2012). According to this approach, two broad clusters underpin moral judgment. On one hand, the two *individualizing foundations* curb exploitation from groups. These foundations represent concern about harm/care and concern about fairness/justice. On the other hand, the *binding foundations* exist to protect and preserve social groups. There are three binding foundations: a concern about purity, a loyalty to groups, and respect for authority. According to moral foundations theory, the individualizing and binding foundations emerged in human evolution as cognitive mechanisms to navigate threat and maximize survival. Research has demonstrated that the *binding* foundations are strongly intertwined with authoritarianism. Federico et al. (2013) showed that right-wing authoritarianism is related to the binding foundations, with the correlation between authoritarianism and the authority/loyalty foundation exhibiting the most prominent relationship. These evolutionary accounts suggest that authoritarianism may be, to some extent, a part of human psychological architecture (see also Sinn & Hayes, 2018).

7.2. Heritability

In addition to authoritarianism's possible evolutionary basis, scholars have identified a genetic foundation for the trait (for a discussion of genetics and politics see Settle & Detert, Chapter 8, this volume). McCourt, Bouchard, Lykken, Tellegen, and Keyes (1999) used the classical twin design to explore whether authoritarianism is partially heritable. By collecting data from monozygotic and dizygotic twins reared together as well as twin pairs separated when young, McCourt et al. estimated the proportion of variation in authoritarianism scores attributable to genetics, common environment, and unique environmental causes. In their data, roughly one-half the variation in authoritarianism scores were attributable to genes. Ludeke, Johnson, and Bouchard (2013) similarly document the heritability of authoritarianism, finding that authoritarianism is a component of a partially heritable *traditionalism* worldview. Using two sets of monozygotic and dizygotic twins, Lewis and Bates

(2014) estimated that 61% of the variation in RWA was genetic. They also found that measures of ingroup favoritism, authoritarianism, and concern for norm maintenance shared the same genetic underpinnings. Their data also suggests that ingroup favoritism and authoritarianism may share a common environmental basis as well.

It is important to note that estimates of heritability from twin designs do not tell us anything about what the pathway from genes to authoritarian attitudes may be. There could be yet-unknown biological or neurological factors that predispose people toward authoritarianism. Alternatively, heritability could be a function of a *gene-environment correlation*: genes may influence the environments that people select into, and it is those environments that influence the development of authoritarianism.

Evolutionary and genetic explanations suggest that authoritarianism has deep roots in human cognition and biology. However, a notable limitation of this work is that the mechanisms by which authoritarianism is expressed are not specified. If authoritarianism is an evolved, adaptive orientation, surely it must be practiced in various ways, such as emotional reactions. We have reviewed authoritarianism research that argues that authoritarianism is influenced or activated by certain types of threat. There is some evidence of biological differences in how authoritarians versus non-authoritarians respond to threat. LePage et al. (2020) show that authoritarianism correlates with two measures of parasympathetic nervous system activation: tonic heart rate and heart rate variability. These indicators correlate with self-regulation, coping with threat, recovery, and aggression. This suggests that there may be biological differences in how authoritarians cope with environmental stress and threat.

7.3. Personality and Authoritarianism

Many studies have provided evidence of a relationship between authoritarianism and personality. An early account of this came from Adorno et al. (1950), who argued that intolerance of ambiguity and cognitive rigidity were closely related to authoritarianism (see also Frenkel-Brunswick, 1949). Rokeach (1956/1960), developed the concept of dogmatism—a closed organization of beliefs—as a less ideologically oriented alternative to authoritarianism in *TAP*. He argued that dogmatism, unlike authoritarianism, could be found on the political left and right. However, studies consistently found that dogmatism is positively correlated with right-wing authoritarianism (Duckitt, 2009). More recently, Altemeyer (1996) developed a balanced, reliable, and non-ideological measure of dogmatism and found correlations of approximately .5 with his RWA measure.

There have also been many studies that have examined the relationships between the Big Five personality dimensions and authoritarianism. From a variety of samples across nations, authoritarianism is most consistently related to openness to experience and, to a lesser extent, conscientiousness (Sibley & Duckitt, 2008).² Authoritarianism is largely uncorrelated with neuroticism, agreeableness, and extraversion. The relationship between authoritarianism and openness is consistent with the earlier findings on intolerance of ambiguity and dogmatism as these constructs are facets of the broad dimension of openness or closely related to it. The relationships with openness to experience and intolerance of ambiguity suggest that authoritarianism may be based, to some extent, on discomfort with novelty or social complexity—as would be aroused by diversity and social change.

7.4. The Social Environment and Learning

Authoritarianism may have genetic and evolutionary foundations. Yet, these causes do not preclude a pervasive impact of one's social environment, which research shows also exerts a well-documented role. *The Authoritarian Personality* offered one of the earliest explanations for the emergence of authoritarian tendencies, citing the role of childrearing experiences. The focus in *TAP* was Freudian in nature, seeking to understand how childrearing patterns contribute to the authoritarian syndrome. High authoritarians were more likely to recall a "distant, stern father, with a bad temper, and a barrier between family and son, as opposed to the picture of a warm, demonstrative father." The mother, on the other hand, was generally "sacrificing, kind, submissive person" (Adorno et al. 1950, p. 366). In *TAP*, authoritarians view the family in competitive terms, often stressing the role of heredity and an "aristocratic superiority" (p. 358). Authoritarians were more concerned with familial images of status, power, and dominance. Ultimately, the "stern and dominant" father and "sacrificing, kind, and submissive" mother would create an environment in which the child will repress hostility, perhaps then projecting upon threatening outgroups (Adorno et al. 1950).

Such Freudian explanations fell out of favor in the latter half of the 20th century, due in part to researchers' inability to empirically replicate many of the key developmental tenets found in Freudian theory (Westen, 1998). It was not until Bob Altemeyer's *Right-Wing Authoritarianism* (1981) that an alternative, more empirically based argument was advanced. As indicated earlier, the "social learning" approach Altemeyer developed conceives of RWA as an *attitude*, not a personality syndrome deeply rooted in early life. Authoritarian attitudes emerge in development through direct experience with the social world. Altemeyer (1981) found little evidence to suggest that authoritarianism emerges in development in response to childrearing patterns, as suggested in *TAP*; rather, authoritarianism represents the learned accumulation of life experiences. Parents provide a large share of the input, as does one's community, educational experiences, news, and entertainment. With respect to the role of the early family environment, Altemeyer's (1981) insight suggests that parenting content, not parenting style, shapes authoritarian beliefs. Children are likely to become authoritarian because their parent(s) is perhaps authoritarian, not because of a unique childrearing style. However, it is also important to recognize that correlations between parent's and children's levels of authoritarianism could be a result of shared genes as well as socialization.

Duckitt (2001) extends these ideas, by exploring the attitudes, values, and beliefs that contribute to RWA. In his model, a person's socialization will inform beliefs and values, which influence worldviews, then ideologies and political beliefs. Duckitt (2001) shows that adults who report growing up in a punitive environment are then more likely to place value in social conformity (over personal freedom). This tendency toward conformity may lead one to adopt a worldview in which world is seen as a dangerous and threatening place, which in turn leads to authoritarianism.

Weber and Federico (2007) shed further light on the effects of parental socialization by developing an *attachment* theory of authoritarianism (see Shaver & Mikulincer, 2009; Mikulincer & Shaver, 2003). Through socialization, children form a set of social expectations—known as *attachment patterns*—rooted in the extent to which the primary caregiver meets the child's psychological and physical needs. *Insecurely* attached individuals

are generally more preoccupied with abandonment and experience heightened degrees of interpersonal distrust and fear. Weber and Federico (2007) found that anxious attachment predicted RWA scores, and, as Duckitt's model suggests, it is mediated by dangerous world beliefs. The

Among the most consistent correlates of authoritarianism is educational attainment. Increasing levels of education are virtually always associated with lower authoritarianism (Simpson, 1972; Stubager, 2008). It is not clear, however, exactly how the correlation comes about, or even if education reduces authoritarianism. In a summary of relevant literature, Stubager (2008) finds three possible causal mechanism that could produce this relationship. Education could foster psychological security, thus reducing the extent to which people are personally threatened by social change and diversity. An alternative way in which education could reduce perceptions of threat is via knowledge and cognitive sophistication. Greater knowledge and sophistication may increase an understanding of the diversity of people and values in the world which should make diversity appear less unusual and unfamiliar. Finally, education may directly instill values that oppose authoritarianism. Educational institutions in many countries teach about toleration and democratic norms. And education exposes students to teachers and, potentially, other students who value diversity and tolerance. It is also possible that some of the association of education and authoritarianism may be non-causal. For example, those low in openness to experience may be less inclined to pursue higher levels of education at the same time it independently leads to greater authoritarianism, thus leading to a spurious correlation between the two.

Education also has informal effects that may affect levels of authoritarianism. Schools immerse students in social networks—groups of friends who are influences on each other's beliefs and values (Jennings & Niemi, 1968). In several studies, Altemeyer (1988) asked students to report on experiences they had, both those that should make them more comfortable with nonconformists and alternative lifestyles and those that should make them less comfortable. In each study, responses to his "experiences" scale were highly correlated with RWA scores ($r > .7$). Of course, as Altemeyer recognized, this association could be a consequence both of social experiences conditioning levels of authoritarianism and pre-existing levels of authoritarianism influencing the choices people make about the types of people they associate with. This uncertainty about causality is, unfortunately, characteristic of much of the existing research on the determinants of authoritarianism. Long-term socialization studies are expensive and difficult to undertake but they probably represent the best way to make progress in this area.

8. THE MEASUREMENT OF AUTHORITARIANISM

Since the publication of Adorno et al. (1950), the predominant method for measuring authoritarianism has been multiple item scales made up of attitude statements asked on an agree-disagree scale. The first version of this was the F-scale developed in Adorno et al. As we noted earlier, the F-scale was designed to tap into the fascistic tendencies inherent to the authoritarian syndrome. Since their conceptualization of authoritarianism was based on nine interrelated syndromes, the questions making up the F-scale were quite heterogeneous. For example, two questions were "Nowadays more and more people are prying into

matters that should remain personal and private” and “Every person should have complete faith in some supernatural power whose decisions he obeys without question.”

Methodological investigations of the F-scale revealed two major problems. First, all the questions were worded in the same direction, so that an agree response corresponds with the authoritarian response. However, research has demonstrated that some individuals have a tendency to agree with statements they are presented with. This is known as acquiescence bias. Acquiescence bias is a potential confound when using the F-scale. Some amount of the variance in the scale may reflect acquiescence tendencies rather than authoritarianism, *per se*. If acquiescence bias confounds the measurement of authoritarianism, that bias may also contaminate the estimated relationship of authoritarianism with other variables. Second, analyses of the F-scale indicated that it was not unidimensional; the nine syndromes that the measure was designed to tap did not, in practice, sufficiently cohere to produce a reliable, single scale (see Altemeyer, 1981).

Altemeyer's (1981/1988) *Right-Wing Authoritarianism* scale was largely born out of the critiques of *The Authoritarian Personality*. From numerous questionnaires administered to his students, Altemeyer developed attitudinal statements that balance for acquiescence bias: for half of the questions, agreement indicated authoritarianism and for the other half, disagreement was the authoritarian response. Altemeyer also found that it was possible to create a more reliable, homogeneous measure by limiting the focus to just three of the components proposed by Adorno et al.: conventionalism, authoritarian submission, and authoritarian aggression. The RWA scale was originally 17 items in length, though Altemeyer eventually expanded it to 30 questions (Altemeyer, 1988). It has been translated into several other languages and shortened to various lengths to make it easier to include on non-student-based studies. Since its development in the 1980s, the RWA scale has been, by far, the most widely used measure of authoritarianism.

Despite its use in a very large number of studies, there are potential problems with the RWA scale that are not widely recognized. While Altemeyer's goal was to produce an authoritarianism scale that is unidimensional, several recent papers have shown that the three components of the scale are, in fact, empirically distinguishable (Funke, 2005; Duckitt et al., 2010; Duckitt & Bizumic, 2013; Dunwoody & Funke, 2016). When questions are written to cleanly measure just one of these three components, factor analyses on multiple samples in several countries show that a three-factor model fits much better than a one-factor model. While the three factors are positively correlated in all of the national samples that have been reported in these studies, some of the inter-factor correlations are weak to moderate in some cases. In general, the smallest correlations are between the conventionalism and aggression factors (labeled as traditionalism and authoritarianism by Duckitt et al., 2010, and Duckitt & Bizumic, 2013). In a Romanian sample included in Duckitt et al., the only significant correlation among the factors was between submission and aggression ($r = .44$). Duckitt and Bizumic present results from a Serbian sample with inter-factor correlations that range from .17 to .25.

Importantly, there is also evidence from these and other studies that the three factors have different associations with variables like prejudice and intolerance that authoritarianism should predict. For example, in a New Zealand sample, Duckitt and Bizumic find that the aggression (authoritarianism) factor predicts prejudice toward “dangerous groups,” submission (conservatism) predicts prejudice toward “dissident groups,” while conventionalism (traditionalism) has no additional significant effect on prejudice toward these

groups. In another study, Ludeke, Klitgaard, and Vitriol (2018) found that the authoritarian aggression factor was the key predictor of support for Donald Trump in the 2016 American presidential election with all three components included in the analysis. Neither of the other two factors were significant predictors.

Evidence that measures of RWA are multi-dimensional raises concerns about the measurement and conceptualization of authoritarianism. A general requirement for scale development is that the measure is unidimensional—the common variance in the items is a function of a single latent construct. It is possible to combine questions that measure the three authoritarianism factors into a single measure. But what is that measure tapping if items in the scale are measuring somewhat different underlying constructs? And, as studies of the dimensionality of RWA have shown, the three factors frequently have different relationships to other social and political variables. Is a single RWA measure therefore obscuring relationships that would be observed using three separate measures?

The dimensionality of RWA also has implications for our understanding of the construct of authoritarianism. If conventionalism, submission, and aggression are somewhat distinct factors, how do we understand exactly what authoritarianism is? For Altemeyer, (right-wing) authoritarianism is the conjunction of the three components. This assumes that high levels of authoritarianism are always manifested by high scores on all three of the factors. As the recent studies of the multi-dimensionality of RWA show, however, it is not uncommon to find people who are high on one of the factors but not on the other two. What identifies people high in authoritarianism if the three factors are not highly inter-correlated?

The attitudinal statements in the RWA scale also raise concerns about the use of the scale in statistical models to predict political policy preferences and support for political parties and candidates for office. One problem is that many questions in the RWA scale ask people's attitudes toward groups and issues that are often the target of debates over government policies. Consider the following RWA items:

Women should have to promise to obey their husbands when they get married.

God's laws about abortion, pornography, and marriage must be strictly followed before it is too late, and those who break them must be strongly punished.

You have to admire those who challenged the law and the majority's view by protesting for women's abortion rights, for animal rights, or to abolish school prayer. (reverse worded)

Homosexuals and feminists should be praised for being brave enough to defy "traditional family values." (reverse worded)

What do we learn if responses to these questions are correlated with people's policy preferences on issues like gay marriage, abortion, and women's equality? Relationships like this are virtually tautological—attitudes toward social groups "predict" preferences on policies affecting these groups. The inclusion of statements like these also raises concerns about the relationship between authoritarianism and ideology. Is someone who agrees with the first two of these statements and disagrees with the second two authoritarian or do they just hold conservative beliefs? The relationship between authoritarianism and conservatism should be subject to empirical analysis, not built into a measure of authoritarianism.

A second potential problem with the RWA scale in models of party and candidate support is that the language in some of the items increasingly resembles rhetoric used by right-wing politicians and media figures. Here are three examples from the RWA scale (all answered on an agree-disagree scale):

Our country desperately needs a mighty leader who will do what has to be done to destroy the radical new ways and sinfulness that are ruining us.

The only way our country can get through the crisis ahead is to get back to our traditional values, put some tough leaders in power, and silence the troublemakers spreading bad ideas.

Our country will be great if we honor the ways of our forefathers, do what the authorities tell us to do, and get rid of the “rotten apples” who are ruining everything.

A large body of research in political science shows that citizens often adopt positions advocated by political leaders that they support (Lenz, 2013)—leaders provide policy cues to voters. If political leaders adopt rhetoric similar to what is found in the RWA scale, it stands to reason that some voters may show support for items on the RWA scale, not because they are necessarily authoritarian, but rather, these voters are absorbing policy cues from trusted political leaders.

There are two issues that need to be distinguished. First, is authoritarianism itself endogenous to political rhetoric? We will return to this question when we discuss other authoritarianism measures. Second, is a measure of authoritarianism endogenous? This is a measurement problem that would hinder studies of the political effects of authoritarianism. If authoritarianism is then used to predict support for political leaders, this leads to an inherent confound: one is predicting support for right-wing politicians from items that resemble the rhetoric of the same right-wing politicians. It is a well-established principle in empirical social science that a correctly specified regression models requires all predictor variables be unaffected by changes in the dependent variable in the model. The exogeneity assumption is problematic in political applications of right-wing authoritarianism. Two recent analyses of panel data in the United Kingdom (Van Assche et al. 2019) and New Zealand (Satherly et al. 2021) demonstrate this. Both studies find that changes in RWA over time are predicted by prior political partisanship. Therefore, contemporaneous correlations of RWA and party support are potentially confounded by the fact that RWA is endogenous to partisanship.

In the early 1990s, Stanley Feldman (see Feldman & Stenner, 1997) implemented an altogether different approach to the measurement of authoritarianism. He developed a four-item childrearing scale, asking respondents to choose between pairs of childrearing values:

Although there are a number of qualities that people think children should have, every person thinks that some are *more important* than others. Although you may feel that both qualities are important, please tell me which one of each pair you think is *more important* for a child to have.

Would you say it is *more important* for a child to be INDEPENDENT or RESPECTFUL OF THEIR ELDERS?

Would you say it is *more important* for a child to be OBEDIENT or SELF-RELIANT?

Would you say it is *more important* for a child to be WELL BEHAVED or CONSIDERATE?

Would you say it is *more important* for a child to be CURIOUS or GOOD MANNERED?

This measure is grounded in the social cohesion/conformity models of authoritarianism previously discussed. If people want members of society to conform to societal norms and respect political leaders who enforce those norms, they should want to socialize children (and thus adults) to be respectful, obedient, well behaved, and good mannered. Responses to these (dichotomous) questions yield a scale with categories ranging from 0 to 4 based on the number of the conformity values that people choose out of the four value pairs.

This measure has now been included in a number of national surveys (every American National Election Study presidential year survey since 1992 except for 1996, several waves of the most recent online British Election Study, a French panel study spanning the 2017 national elections, recent national election studies in Germany and Switzerland, and others). Englehardt, Feldman, and Hetherington (2021) show that this measure is highly correlated with a short RWA-type measure. It predicts a wide range of policy preferences and measures of prejudice that authoritarianism is expected to be associated with (Hetherington & Weiler, 2009/2018; Velez & Lavine, 2017). And it is strongly correlated with support Donald Trump in 2016 (Weber et al., 2017), and right-wing parties in France and Germany (Hetherington & Weiler, 2018; Vasilopoulos & Lachat, 2018).

A major advantage of this measure in analyses like these is that questions do not have obvious political content—political debate rarely centers around childrearing practices. So, if this measure correlates with political outcomes, it is unlikely that it suffers from the endogeneity problem cited above; responses to the four value pairs probably do not strongly reflect contemporary political discourse. Using two American national panel studies, Englehardt et al. (2021) find no evidence that a range of political attitudes, candidate attitudes, and partisanship are associated with changes in the childrearing measure over time.

A limitation of the measure is that it is based on dichotomous responses to just four questions. This creates two methodological problems. First, the reliability of the measure is less than desirable (typically in the range of .6 to .65). Second, the distribution of responses to the measure yields too many people with scores of 0 and 4. This makes it difficult to distinguish those who are very high and very low in authoritarianism. Englehardt et al. (2021) have identified four additional value pairs that increase the reliability of the (eight-item) measure and increase its variance. They show that the estimated effects of the new eight item measure on a range of political variables are, on average, 50% larger than those obtained from the original four-item scale.

Another measure that is conceptually similar to the childrearing scale uses items from the Schwartz (1992) value inventory. One of the two dimensions that Schwartz derives to describe the configuration of values is anchored at one end by social conformity values (conformity, tradition, and security) and, at the opposing side, personal autonomy values (self-direction and stimulation). Subtracting a summed score of the personal autonomy values from the sum of the social conformity values produces a measure of the social conformity-autonomy dimension. Feldman (2003) showed that this value measure is highly correlated with RWA. This measure has been successfully used in studies of authoritarianism (see for example, Cohrs et al., 2005; Norris & Inglehart, 2019; Claassen & McLaren, 2020). The inclusion of the Schwartz value inventory on the European Social Surveys allows researchers to investigate effects of authoritarianism in these rich data sets.

9. A RETURN TO LEFT-WING AUTHORITARIANISM

As we have noted, one of the earliest critiques of *The Authoritarian Personality* was that it ignored authoritarianism on the political left (Eysenck, 1954; Shils, 1954). Shils argued that the basic characteristics of authoritarianism could be observed in the communist leadership

of the Soviet Union and the submission of Russians to Stalin's rule just as clearly as in Nazi Germany. In the decades since this issue arose, the specter of left-wing authoritarianism (LWA) has refused to die. In the last few years, new studies have appeared that attempt to develop valid, reliable measures of LWA, provide evidence that it can be found in Western societies, and identify correlates of LWA that show that it has foundations similar to RWA.

An early attempt to address concerns about the ideological character of authoritarianism came from the work of Rokeach (1956/1960) on dogmatism. Rather than focusing on authoritarianism on the political right, he argued that it was more fruitful to approach the study of authoritarianism by developing a nonideological conceptualization and measure of authoritarian tendencies. Rokeach hypothesized that the core of authoritarianism—whether on the political right or left—was a fixed, closed-minded belief system. In addition, Rokeach developed a self-report measure of dogmatism that he used in numerous studies on different samples. Unfortunately, the dogmatism scale included heterogeneous attitude statements with low inter-item correlations and featured the same acquiescence biases that plagued the F-scale. Even though Rokeach constructed the scale to tap authoritarianism across the political spectrum, studies consistently found that it was correlated with authoritarianism on the right (Stone, 1980; Altemeyer, 1996). In his 1980 review of research (largely based on Rokeach's dogmatism scale) that attempted to find authoritarianism on the left, Stone (1980, 13) concluded that "The present review of theoretical and empirical treatments of left-wing authoritarianism suggests that the concept may have no foundation in fact."

More recently, Altemeyer (1996, p. 201) narrowed the conceptualization of dogmatism to a "relatively unchangeable, unjustified certainty." Importantly, he also created a new self-report dogmatism scale that is much more reliable than Rokeach's measures and has items that are balanced for agreement response set. Despite using statements with no obvious ideological content, Altemeyer found correlations between his dogmatism measure and RWA of approximately .5. Consistent with studies that used Rokeach's measure, closed-mindedness—as tapped by Altemeyer's dogmatism scale—is strongly correlated with *right-wing authoritarianism*.

In addition to his studies using the dogmatism measure, Altemeyer (1996) attempted to develop a direct measure of left-wing authoritarianism. His strategy was to take statements included in his RWA measure and re-word them so that they would reflect left-wing versions of the three components of his RWA scale: submission ("a high degree of submission to authorities who are dedicated to *overthrowing* the established authorities in one's society"), aggression (a general aggressiveness directed against the established authorities, or against persons who are perceived to support those authorities"), and conventionalism ("a high degree of adherence to the norms of behavior perceived to be endorsed by revolutionary authorities") (Altemeyer, 1996, 219). Examples of statements in the LWA measure are:

A leftist revolutionary movement is quite justified in attacking the Establishment, and in demanding obedience and conformity from its members.

Even a revolutionary left-wing movement dedicated to overthrowing the present, totally unjust right-wing system does NOT have the right to tell its members how to act, dress, think, etc. (reverse worded)

LWA, for Altemeyer, is thus an uncritical willingness to submit to a revolutionary, left-wing movement that desires nothing short of overthrowing established governments.

Perhaps not surprisingly given the extreme ideological character of many of the items in the scale, Altemeyer found vanishingly few of his students (or their parents, in one sample) who scored high on the LWA measure. Similar results were found by Van Hiel, Duriez, and Kossowska (2006) in two non-random samples of adults in Belgium. Van Hiel et al. modified Altemeyer's LWA scale by dropping the conventionalism questions. They argued that "conventionalism is a belief system that essentially opposes ideologies that promote social change" (Van Hiel et al., 2006, 774). Their modifications of Altemeyer's scale did not help them find evidence of LWA in their two samples. Van Hiel et al. went further by recruiting people who were members of extreme left-wing organizations: Belgian communist and Stalinist groups. While the sample size was small (20 in the extreme left-wing groups), 13 of those group members scored above the midpoint of the LWA scale with two scoring at the scale maximum. This provides some validation for their LWA measure. Based on these findings, the authors concluded: "However, these results also make it clear that the presence of LWA in Western societies seems to be limited to very specific political movements that do not elicit much support in the mass public. As such, LWA is a marginal phenomenon in political life that is not easily found in convenience samples" (Van Hiel et al., 2006, 787).

Conway et al. (2018) adopt a qualitatively different strategy to measure left-wing authoritarianism. Rather than developing an altogether different scale, Conway et al. reworded items from the RWA scale "to direct the focus of the item on supporting authoritarian leaders that liberals would be more likely to agree with" (Conway et al., 2018, 1055). Like the RWA scale, several statements merely reflect left/right political views and have no obvious authoritarian tendency (e.g., "Progressive ways and liberal values show the best way of life"). However, some of these modified items do capture the flavor of authoritarian aggression (e.g., "Our country desperately needs a mighty and liberal leader who will do what has to be done to destroy the radical traditional ways of doing things that are ruining us." And "What our country really needs is a strong, determined leader who will crush the evil of pushy Christian religious people, and take us forward to our true path."). Their rewording of RWA items to reflect "left-wing authoritarian leaders" raises the question of who those leaders are. Consider the following statement from the RWA scale and its LWA counterpart:

RWA: It's always better to trust the judgment of the proper authorities in government and religion than to listen to the noisy rabble-rousers in our society who are trying to create doubts in people's minds.

LWA: It's always better to trust the judgment of the proper authorities in science with respect to issues like global warming and evolution than to listen to the noisy rabble-rousers in our society who are trying to create doubts in people's minds.

Is casting doubt on scientists with respect to issues like global warming a reflection of authoritarian submission? More generally, with the exception of scientists, it is not clear from the items in this LWA scale who the left-wing authority figures are that left-wing authoritarians are submissive to.

Do left-wing authoritarians exhibit the same characteristics as authoritarians on the right? Conway et al. randomly assigned subjects to answer either the RWA or LWA scale. Those in the RWA condition also answered the Modern Racism Scale (McConahay, 1986) or a reworded version targeting environmental groups. They also answered either the Rokeach dogmatism scale or a reworded version focusing on religion. Those in the LWA condition

were presented with a version of the Modern Racism Scale focusing on religious groups and a reworded dogmatism scale that deals with environmental issues. There was thus no invariant content across the two conditions to compare the psychological characteristics of high scorers on the LWA and RWA measures. In two samples, Conway et al. found that the correlations of LWA and RWA with their respective, targeted versions of the Modern Racism Scale were large and equivalent in size. In both samples, the correlation of RWA with the conservative version of the dogmatism scale was almost twice as large as the (significant) correlation of LWA with the liberal version. And, in both samples, self-identified liberals were *higher* in LWA than were conservatives on the RWA measure.

Costello et al. (2022) also approach the question of left-wing authoritarianism by first constructing their own LWA measure but in a manner quite different from that proposed by Conway et al (2018). Their LWA scale consists of attitudinal statements believed to tap left-wing authoritarianism. Factor analyses yielded three sub-factors that were labeled anti-hierarchical aggression, anti-conventionalism, and top-down censorship. Like Altemeyer's LWA scale, many of their statements are fairly extreme, especially those in their anti-hierarchical aggression factor. For instance, consider these items:

When the table are turned on the oppressors at the top of society, I will enjoy watching them suffer the violence they have inflicted on so many others.

Most rich Wall Street executives deserve to be thrown in prison.

If a few of the worst Republican politicians were assassinated, it wouldn't be the end of the world.

To measure anti-conventionalism, Costello et al. use these (among others):

Deep down, just about all conservatives are racist, sexist, and homophobic.

It is important that we destroy the West's nationalist, imperialist values.

In contrast, many of the statements in the top-down censorship factor reflect contemporary attitudes concerning offensive and racist speech:

University authorities are right to ban hateful speech from campus.

I should have the right not to be exposed to offensive views.

Costello et al. report the results of analyses from multiple samples that included a wide range of measures of personality, cognitive rigidity, and psychopathology. Diverging from much recent research that shows that there are substantial differences between right-wing authoritarianism and social dominance orientation (following Duckitt's 2001 Dual Process Model), Costello et al. compare associations with their LWA scale to patterns of relationships with both RWA and SDO. While there are some similarities between their LWA scale and the RWA scale in terms of their relationships with the psychological measures in their samples, in some cases the pattern of relationships makes LWA look more like the counterpart to SDO than RWA—particularly for anti-hierarchical aggression. Their decision to contrast their LWA measure with a combination of RWA and SDO makes it more difficult to determine what, if anything, are the common underlying features of left-wing and right-wing authoritarianism, as measured by the RWA scale.

Costello et al. provide some evidence that those who score high on their LWA measure share some psychological characteristics with high scorers on RWA. In many of their

analyses they present partial correlations of LWA (and RWA) with a range of variables, controlling for left-right political orientation (LWA is highly correlated with measures of political ideology). There are some notable divergences, however. As Altemeyer found, dogmatism is strongly correlated with RWA; it is weakly correlated with Costello et al.'s LWA scale. Like the Altemeyer and Van Hiel et al. LWA measures, it is unclear how many people in Western societies would score high on this measure, especially for the anti-hierarchical aggression and anti-conventionalism factors.

What the Conway et al. and Costello et al. approaches have in common is that they begin their studies of left-wing authoritarianism by constructing scales (which are quite different from each other) that are designed to measure authoritarianism on the left, to compare to right-wing authoritarianism. Both argue that it is not possible at this point—or potentially in the future—to develop a measure of authoritarianism that is ideologically neutral. This approach has some major implications, not only for measuring authoritarianism, but also for its conceptualization.

In terms of measurement, the clear left-wing content in these LWA scales creates the same endogeneity problems for researchers that we noted for Altemeyer's RWA scale. What does it mean for our understanding of the nature of authoritarianism if it is inextricably bound up with ideology? It is then possible that the motivational basis of right-wing and left-wing authoritarianism are different? In the Costello et al. formulation, left-wing authoritarianism reflect a desire to overthrow the current political and economic system in the United States. Is this, motivationally, equivalent to the desire of those high in right-wing authoritarianism to defend ingroup norms and enforce social conformity?

This raises the question of whether authoritarianism is a deep psychological phenomenon or just a series of attitudinal and behavioral characteristics that can be observed in some people on the left and right. And are those characteristics necessarily reflections of authoritarianism? For example, it is well known that people on the political left and right can be intolerant of groups that they see as a threat (Sullivan et al., 1982; Crawford & Pilanski, 2014). Any conceptualization of authoritarianism should go beyond just finding that some people on the left and right can be intolerant of those who hold divergent beliefs.

10. THE POLITICAL EFFECTS OF AUTHORITARIANISM

As we have shown, a consistent finding to emerge in authoritarianism research is that a non-trivial portion of citizens in democratic societies may voluntarily abandon their personal liberties for collective security. Also, as we have suggested, authoritarianism is not inherently right- or left-wing. Instead, how authoritarianism is practiced largely depends upon one's group, and the position of that group within the broader society. However, in practice, authoritarianism does consistently relate to support for right-wing populist parties, anti-democratic attitudes, support for autocratic leaders, and a fierce defense of conventionalism and the status quo. Though authoritarianism may not be an exclusively right-wing phenomena, the preponderance of empirical evidence suggests that those with right-leaning tendencies tend to also be more authoritarian (Eysenck, 1954; Brown, 1965/

2004; Rokeach, 1960; Altemeyer, 1998). The prioritization of collective security over personal autonomy explains, in part, the rise of authoritarian parties across the globe (Norris & Inglehart, 2019).

It is important to recognize that there is an important distinction between *authoritarian* leaders and *authoritarians* in the mass public. While our focus has primarily been on the latter—this chapter is situated to understand the human tendency to submit—here we consider the former as well. In particular, *how does authoritarianism in the mass public produce authoritarian leaders, and in what ways do authoritarian leaders package policies that resonate with authoritarian voters?* In this section, we take up the *politicization* of authoritarianism, exploring the myriad ways that authoritarianism is politically expressed.

10.1. Authoritarianism Submission and Political Party Support

Empirically, authoritarianism tends to align with support for right-wing political parties. In their book, *Cultural Backlash: Trump, Brexit, and Authoritarian Populism*, Norris and Inglehart (2019) situate political parties according to their authoritarian and populist orientation. Here, it is useful to think of *populism* as a generally anti-establishment and anti-elitist orientation. Throughout Western history, populist parties have been both *left* and *right* in their ideological orientation. And, while populism continues to be expressed among liberal and conservative parties, from 2010 to 2020 the world witnessed substantial increases in electoral success for *right-wing, authoritarian populism* (Norris & Inglehart, 2019). In the United States, the Republican Party under Donald Trump similarly exhibited characteristics of authoritarian populism.

Research has demonstrated that authoritarians gravitate toward authoritarian populist parties, and their oftentimes charismatic leaders. Vasilopoulos et al. (2019), for instance, show that after the 2015 Paris attacks, authoritarians were more likely to support the far-right National Front. Similarly, Bakker, Schumacher, and Rooduijn (2021) found that authoritarianism is related to support for the Britain's far-right UKIP. Schmidt, Darowska, and Gloris (2017) similarly find that support for conformity predicts support for the Alternative for Germany (AfD), also a far-right party (see also Hetherington & Weiler, 2018).

Cognitive linguist George Lakoff (2008) suggests that two dominant metaphors dominate ideological thinking and partisan politics in the United States. Lakoff argues that preferences regarding the size, scope, and function of government are extensions of citizens' views toward child socialization, with the political-left-viewing child, and by extension governing, arrangements in a "nurturant," egalitarian manner. The political right in the United States, on the other hand, has advanced a more "disciplinarian" vision, focusing on traditionalism and decidedly more authoritarian parenting preferences. Using the childrearing values, which we have discussed as a measure of authoritarianism, Barker and Tinnick (2006) draw on the American National Election Studies (ANES) to provide empirical evidence for Lakoff's expectations. They showed that the childrearing measure predicts a wide range of conservative political values and issue preferences, even in models with extensive controls for attitudinal and demographic variables that the childrearing measure is

correlated with. The conservative issue preferences associated with authoritarianism should then incline people to support right-wing parties and leaders.

Why are authoritarians attracted to “strong man” political parties? Norris and Inglehart (2019) show that authoritarian populists parties draw on themes and metaphors that advance an “us” versus “them”—and by extension “strong” versus “weak”—narrative. The authoritarian populist often scapegoats, highlighting the aggrieved status of their political or social group. The authoritarian populist’s “group” is cast as victimized, perhaps affected adversely by changing social norms, demographic diversity, and a threat to traditional values. Consider Donald Trump’s presidential announcement speech, where he notes, “Our country is in serious trouble. We don’t have victories anymore,” and “the U.S. has become a dumping ground for everybody else’s problems.” He goes on declaring, “when Mexico sends its people, they’re not sending their best. They’re not sending you. They’re not sending you. They’re sending people that have lots of problems, and they’re bringing those problems with us. They’re bringing drugs. They’re bringing crime. They’re rapists. And some, I assume, are good people.”³ Federico, Feldman, and Weber (2022) show that the ascendance of Donald Trump was due primarily to a punctuated multi-decade process. From 1992 to 2004, authoritarians sorted into the Republican Party (Hetherington & Weiler, 2009), a process that expanded greatly during the Trump presidency (Federico et al., 2022), likely due in part to the explicit authoritarian rhetoric that Trump frequently employed. Scholarly work has established a strong connection between authoritarianism and support for Donald Trump in the 2016 American presidential election (Bakker et al., 2021; MacWilliams, 2016; Feldman, 2020; Womick et al., 2019; Ludeke et al., 2018).

10.2. Social Cohesion, Group Aggression, and the Preservation of Law and Order

Authoritarianism is often predictive of law-and-order policies that preserve the status quo. For instance, Hetherington and Suhay (2011) examine citizen response to the September 11 terrorist attacks. They find that authoritarianism generally predicts civil liberties restrictions, such as warrantless wiretapping, torture, and opposition to criticizing the president. Feldman (2020) similarly finds that authoritarianism predicts support for carrying national ID cards, wiretapping, and profiling of airport security. Recall that a central tenet to much authoritarianism research is the notion that authoritarians actively defend the (conventional) status quo and aggress against those that threaten or challenge the status quo. Dunwoody and Plane (2019) find that authoritarianism predicts support for removal of unregistered Muslim or Mexican immigrants, and this support persisted even when authoritarian respondents were told the action is unconstitutional.

In addition, authoritarians typically hold negative attitudes toward those who challenge conventional Judeo-Christian norms (Altemeyer, 1981). Authoritarians, for instance, often express aversion to homosexuality (Stenner, 2005; Cohen & Smith, 2016; Malka et al., 2014), as well as abortion, immigration, and criminal leniency (Malka et al., 2014). Authoritarianism is linked to opposition to immigration, LGBTQIA+ rights, and affirmative action (Cizmar et al., 2014). It is diagnostic of negative out-group attitudes in non-US contexts. Authoritarianism has been linked to prejudice in Netherlands (Van Assche et al., 2014), Poland (Bilewicz et al., 2017), Germany (Asbrock et al., 2012), and Italy (Passini,

2017), as well as Australia and New Zealand (Duckitt, 2001; Bizumic & Duckitt, 2018; Duckitt, 2006). The combination of outgroup animosity and socially conservative attitudes helps to explain the attraction of right-wing populist parties and leaders to those high in authoritarianism. Some of these studies that show pronounced effects of authoritarianism on political attitudes and party support used RWA-type measures that we have argued are potentially endogenous to those outcomes. However, many of these studies employed the childrearing measure and they find substantial effects of authoritarianism on support for authoritarian populist parties, conservative social attitudes, and opposition to immigration. The overall conclusions of this section thus seem robust to variation in the measurement of authoritarianism.

11. CONCLUDING THOUGHTS

The study of authoritarianism was initially motivated by social scientists' desire to understand mass support for the Nazi Party in Germany, and the horrors of the Holocaust. A large body of research quickly found relationships between authoritarianism and prejudice, intolerance, punitiveness, and right-of-center political views. As we have shown in this chapter, even with significant changes in the conceptualization and measurement of authoritarianism over the decades since its introduction, recent research continues to document the importance of authoritarianism for understanding animosity toward outgroups as well as social and religious nonconformists, and support for anti-democratic actions and policies. As the world has seen greater migrations of people, authoritarianism has become an important factor in our understanding of why people oppose or support immigration and, as well, often vote for right-wing populist parties and politicians who take strong anti-immigration stands.

While there is a great deal of continuity in studies that document the effects of authoritarianism, we have shown that the conceptualization and theoretical framework underlying the construct has changed substantially over time. Altemeyer's substitution of social learning theory for the Freudian theory of Adorno et al. that had fallen out of favor provided researchers with a more straightforward way of understanding authoritarianism as a cluster of learned social attitudes. However, the "thin" social learning account ultimately lead many researchers (Duckitt, 1989, 2001; Feldman & Stenner, 1997; Feldman, 2003; Stellmacher & Petzel, 2005; Stenner, 2005; Norris & Inglehart, 2019) to a conceptualization that views authoritarianism as a desire for ingroup cohesion and conformity to group norms. As we have discussed, this conceptualization provides a richer framework for studying authoritarianism and, importantly, identifies social and cultural threat as factors that moderate the political effects of authoritarianism. The interaction of authoritarian predispositions and social/political conditions helps to answer a central question: why are the effects of authoritarianism in politics much more pronounced in some places and at certain times and not others?

Despite the rapidly growing body of research on authoritarianism, questions about the nature, consequences, and measurement of the construct remain. If authoritarianism is bound up with a desire to maintain ingroup cohesion, a key question becomes how people identify their ingroup. A person could see their ingroup as the nation, their racial/ethnic group, their religion, or some combination of such groups (see Huddy, 2013). We have

examined some evidence that the effects of authoritarianism are different in minority and majority groups. Perhaps not surprisingly, there are vastly more studies of authoritarianism among majority group members and relatively few studies that examine its dynamics in minority groups. The group cohesion perspective suggests that we can learn more about the dynamics of authoritarianism by broadening the focus of research by comparing its effects in majority and minority groups.

Another question that comes out of the group cohesion models is the identification of the group norms that those high in authoritarianism seek to defend. An implicit assumption in virtually all research on majority group member is that there is a common set of ingroup norms that invoke “traditional” moral values, the privileged status of the majority group, and the value of social, political, and religious institutions. Most obviously, ingroup norms for members of minority groups may be very different. More importantly, this assumes that group norms are fixed and consensual. But this is almost certainly not true. If those high in authoritarianism are motivated to defend group norms, we need to know more about how those norms are perceived. And what is the role of elites in shaping group norms in ways that increase or decrease the deleterious effects of authoritarianism?

There remain deep divisions in how to best measure authoritarianism. Despite the concerns we discussed with its potential endogeneity, many researchers continue to use Altemeyer’s RWA scale or some variant of it. A growing number of large-scale studies are instead employing the childrearing measure. We need to know more about the consequences of these alternative measures for conclusions about effects of authoritarianism in the political domain.

Finally, at this point we think that it is premature to draw firm conclusions about the status of left-wing authoritarianism. A resurgence of research on this topic is just beginning to make its way into peer-reviewed journals. At least two new and quite different measures have been introduced that purport to measure left-wing authoritarianism. And challenges to this new research have not yet been published. Closer attention to left-wing versus right-wing authoritarianism is important, not only for exploring the possibility of anti-democratic attitudes on the political left, but also for our deeper understanding of the nature and origins of the construct of authoritarianism.

NOTES

1. The Dual Process Model name for Duckitt’s model has no relationship with the dual process models of cognition and information processing (see Jerit & Kam, Chapter 15, this volume).
2. Sibley and Duckitt’s (2008) meta-analysis estimated a mean correlation of $-.36$ between openness to experience and authoritarianism.

CHAPTER 21

NATIONAL IDENTITY, PATRIOTISM, AND NATIONALISM

LEONIE HUDDY

CITIZENS form strong psychological attachments to the nation-state which has proven to be a robust and enduring political entity. At certain historical times, national attachments are seen as politically dormant, whereas at other times they are regarded as ascendent (Hobsbawm 1990). In truth, the political power and relevance of citizens' national attachments wax and wane with ongoing events. There has been a resurgence of nationalism in recent times as a diverse array of leaders including Donald Trump (United States), Narendra Modi (India), Jair Bolsonaro (Brazil), and Victor Orban (Hungary) rose to political prominence. Other recent political events reinforce the rising importance of national attachments. The Brexit vote brought home the power of national attachments to fracture supra national alliances and entities. The coronavirus pandemic has fostered exclusionary travel policies, inhibited global movement, and generated talk of vaccine nationalism as wealthy countries hoard vaccines for the use of their citizens. All in all, this is a good time to take stock of research on national attachments and evaluate their political effects.

There are few areas in political psychology as contentious as the study of national attachments, however, which can have positive and negative normative political consequences. This field of research is dominated by perennial questions concerning whether loyalty to a nation fosters pernicious ethnocentrism or serves as a laudatory form of national glue that promotes multi-ethnic and racial cooperation. National attachments clearly have chauvinistic aspects that undercut or dissolve national unity by creating internal divisions and stoking suspicion of outsiders. This chauvinism can manifest as a restriction on welfare assistance to internal ethnic and racial minorities, the denial of assistance to foreigners and immigrant newcomers, or the development of exclusionary national norms that dictate nativist religious, cultural, or linguistic practices (Kymlicka, 2015; Theiss-Morse, 2009).

It is also clear that national attachments foster national solidarity. Miller and Ali (2014) hold this positive view, regarding national attachments as an essential ingredient of modern, Western societies. In their words, residents of multicultural, market-driven nations "will

only be willing to support socially just institutions and policies - particularly those that together make up the welfare state - if they share a common identity with those who are likely to be net beneficiaries" (p. 239). There is a growing body of empirical evidence demonstrating that a shared national identity fosters trust and assistance to co-nationals, promotes cooperative health behavior, and enhances civic engagement (van Bavel et al., 2020; Theiss-Morse 1996; Huddy and Khatib 2007).

The divergent consequences of national attachments are confusing and beg resolution. Why do national attachments sometimes promote and at other times undercut national cohesion? In this chapter, I dig more deeply into the nature and psychology of national attachments to better understand their political consequences. The first order of business is to provide clear and distinct definitions of different kinds of national attachments. The inconsistent use of terminology and measures makes it difficult for researchers working in this area to communicate clearly with one another. We do not need a vast number of concepts to bring clarity to the study of national attachments. I begin with the concept of national identity, a subjective attachment and identification with the nation and co-nationals.

A strong national identity is linked to patriotism which conveys a love of country and adherence to specific national norms, including the behaviors and beliefs expected of a loyal member of the nation. In that sense, patriotism captures specific types of ingroup loyalty. But the exact manifestation and consequences of patriotism depend heavily on national context and the nature of shared national norms. National identity is also related to nationalism, an attachment to the nation that spills over into chauvinism and a dislike of outsiders. A common link to national identity helps to explain why patriotism and nationalism are closely aligned in empirical data. Nonetheless, despite sharing a common national identity, patriots and nationalists can differ sharply in terms of their political beliefs.

The distinction between patriotism and nationalism has been commonplace in political psychology for some time (De Figueiredo and Elkins 2003; Kosterman and Feshbach 1989; Osborne et al. 2017). It can be traced back to *The Authoritarian Personality* (Adorno et al. 1950), a seminal work in which the authors differentiated simple love of country, labeled as patriotism, from *pseudopatriotism*, a "blind attachment to certain national cultural values, uncritical conformity with the prevailing group ways, and rejection of other nations as outgroups." When defined in this way, pseudopatriotism is not identical to nationalism, but shares a common animosity toward foreigners.

These three concepts—national identity, patriotism, and nationalism—provide a parsimonious and effective way to understand the political consequences of national attachments. They also serve as a useful simplification of the myriad concepts developed under the rubric of national attachments, many of which can be folded into or associated with the three basic concepts, as I discuss below.

There are additional theoretical and empirical reasons to distinguish between patriotism and nationalism. First, from an evolutionary perspective, positive ingroup attachments such as patriotism provide a foundation for human cooperation and help to explain the ease with which humans adopt social identities (Brewer 2004; Brewer and Caporeal 2006; see also Petersen, Chapter 7, this volume). In contrast, negative outgroup animosity is a more variable outcome of group life. From an evolutionary perspective, outgroup animosity depends on the presence of intergroup threat and is not a necessary consequence of an ingroup attachment (Brewer 1979). Second, there are empirical grounds on which to divide measures of national attachments into patriotism and nationalism. The two measures are empirically related but also distinct, and their political effects can be classified into two

broad classes of outcomes as discussed below. In simple terms, patriotism is far more likely to unite citizens of a nation whereas nationalism has greater potential to divide them, especially in ethnically diverse societies. Nationalism also generates ethnocentric reactions to foreigners more consistently than patriotism.

Before delving further into the psychology of national attachments, it is important to note that patriotism and nationalism refer to attachments to nation-states. A nation is defined as a group of connected people, specifically those who share common ancestry, history, or culture. In contrast, a state has distinct institutions, territory, and government. The nation-state refers to a state that controls its borders, has distinct institutions, and is also made up of a group of people with a common background, culture, or history. Patriotism and nationalism involve a link to both the national population and respect for state institutions and thus forge subjective ties to a nation and a state. As evidence, both forms of national attachment are undergirded by national identity, by an identification with other members of the nation, and in that sense are aspects of a nation. Patriotism and nationalism are also linked to support for state institutions. Patriotism promotes state-linked behavior such as voting and tax compliance. Nationalism is associated with support for state institutions such as the military and homeland security that protect state borders and engage in conflict with threatening neighboring states. To keep things simple, I use nation as a short-hand term for nation-state throughout this chapter.

1. DEFINING NATIONAL ATTACHMENTS

1.1. National Identity, Patriotism, and Ingroup Attachments

1.1.1. *National Identity and Ingroup Bias*

According to Tajfel, a social identity (or in this case a national identity) involves an individual's "knowledge of his membership in a social group (or groups) together with the value and emotional significance attached to the membership" (Tajfel 1981, p. 255). From this vantage point, national identity involves a cognitive awareness of belonging, and an emotional attachment, to a nation (see Mason, Chapter 24, this volume). Consistent with this definition, *national identity* is defined as a subjective or internalized sense of belonging to the nation that is measured by questions concerning the subjective importance of being a national and a sense of connection to co-nationals (Huddy and Khatib 2007; Huddy 2013). National identity is typically associated with a mild positive bias for one's own country over others, and a preference for co-nationals but does not imply any necessary hatred of outsiders. It creates the foundation for other forms of national attachments and provides the substrate for adherence to national norms. Strong national identifiers are very likely to conform to consensual national norms such as voting (Huddy and Khatib 2007).

1.1.2. *Patriotism and National Pride*

Patriotism is strongly aligned with national identity and has similar consequences, including adherence to national norms. It is commonly defined as "a deeply felt affective attachment to the nation" (Conover and Feldman et al. 1987, p. 1), or the "degree of love for and pride

in one's nation" (Kosterman and Feshbach 1989, p. 271). It involves an inclusive sense of national belonging regardless of citizens' ethnic and religious background (De Figueiredo and Elkins 2003, p. 175). It can fuel positive attitudes toward immigrants and generate trust in a country's institutions (Gross et al. 2009; Huddy and Del Ponte 2019; Satherley et al. 2019). According to Habermas (1996) patriots are bound together in liberal democracies by a political culture, in which citizens "patriotically identify" with civic practices and participatory self-rule. At its essence patriotism is an ingroup attitude that conveys positive feelings about one's own nation and co-nationals but does not necessarily lead to outgroup derogation (de Figueiredo and Elkins 2003). Patriotism also heightens adherence to group norms and generates trust in a country's institutions (Gross et al. 2009). Patriotism is thus most commonly measured by pride in the nation and various aspects of national achievement (Huddy et al. 2021).

National identity and patriotism both involve positive feelings for the nation and generate national solidarity and a liking for co-nationals (Theiss-Morse 2009; Miller and Ali 2014). Patriotism is a more complex concept than national identity, however, because the positive emotions and pride with which it is associated can become tied to specific and not fully consensual forms of patriotic behavior. Reverence for the national flag, standing for the national anthem, serving in the military, or refusing to criticize national leaders have been seen at different times and by varying political subgroups as foundational forms of patriotic behavior. These more specific meanings of patriotism can also generate political conflict to a far greater degree than an internalized national identity. In the United States, those on the political left and right have differed at times on whether support for national symbols such as the flag and anthem, military service, and uncritical allegiance to national authorities constitute proud, patriotic behavior (Hurwitz and Peffley 1999).

1.1.3. *Civic Patriotism, Constructive Patriotism, and Civic Norms*

In addition to identifying with or feeling proud of the nation, researchers have also investigated the specific behaviors or practices deemed normative for good or ideal citizens of a nation. I refer to these as injunctive national norms which are equated with the common meaning and expectations linked to membership of a specific nation. Norms vary across nations, helping to explain why national identity and patriotism can generate different political outcomes in different national contexts. National norms can also vary among subgroups and subcultures within a nation. Researchers have focused on two key understandings of national belonging, developed initially to distinguish among differing national political cultures: (1) civic patriotism and (2) ethnocultural conceptions of the nation (Citrin et al. 1990; Shulman 2002; Wright et al. 2012).

Civic patriotism defines a good citizen as one who obeys the nation's laws, votes in its elections, and adequately fulfills other national obligations and responsibilities such as paying taxes. In the United States, this view of American identity is widely accepted (Citrin et al. 1990). Schatz, Staub, and colleagues develop the related concept of *constructive patriotism*, which is defined as "an attachment to country characterized by critical loyalty" and "questioning and criticism" driven by "a desire for positive change" (Schatz et al. 1999, p. 153). Constructive patriotism is linked to political engagement, and in that sense tied to the concept of civic patriotism and its attendant civic responsibilities. In nations with strong

civic national norms, civic patriotism, general patriotism, and national identity will be related, heightening levels of patriotic civic behavior. In contrast, ethnocultural conceptions of the nation are more divisive and less normative, having far more in common with nationalism than patriotism.

Patriotism can take other forms as well. Symbolic patriotism is linked to reverence for the national flag and anthem (Hurwitz and Peffley 1999). Suhay, Calfano, and Dawe (2016) demonstrate that making symbolic patriotic norms salient increases the prevalence of patriotic behavior. In their study, reinforcing patriotic American norms such as flag flying on the Fourth of July increased Muslim Americans' intention to enact such behavior. In sum, patriotic behavior is defined by national norms, resulting in different patriotic behaviors across countries. Patriotic behavior can include expectations of military service, reverence for the national anthem, a willingness to pay taxes to support a strong social welfare state, or support for overseas humanitarian intervention. Making a patriotic norm salient will increase the relevant patriotic behavior, even as that behavior differs across national contexts.

1.1.4. *Diverse Patriotisms*

The ability of subgroups and subcultures to shape and diversify the meaning of national identity helps to explain the proliferation of various forms of patriotism. Some scholars have identified different and potentially contested meanings of the nation grounded in its founding, history, and culture. The search for more fine-grained meanings of patriotism can be nationally idiosyncratic, resulting in typologies of patriotisms that are more difficult to compare across nations. There has been considerable effort to identify different meanings of American identity and patriotism, for example. Smith (1997) identifies a liberal tradition within American political culture that emphasizes individualism, a civic republican tradition that focuses on community self-governance, and an ethnocultural tradition that reflects the white population's desire for dominance discussed below. Schildkraut (2002) confirms Smith's tripartite conception of national ideology and adds incorporationism as a fourth element that reflects a view of the United States as an immigrant nation.

The diverse meanings of national identity and the proliferation of patriotisms can be observed in other nations. For example, Breidahl et al. (2018) identify a conservative and liberal meaning of Danish identity. A conservative understanding of Danish identity involves adherence to Danish traditions and the view that Danish history and Christianity should be advanced in schools. In contrast a liberal understanding of Denmark entails knowing about Danish culture, participating in civic society, and advocating freedom of religion and speech. Presumably, there are different and potentially idiosyncratic meanings of patriotism and national belonging in every nation, linked to a nation's origins, history, and values.

1.2. Nationalism and an Outgroup Focus

In contrast to patriotism, *nationalism* is defined in political psychology as a sense of "national superiority and dominance" that includes an attachment to the nation (as does patriotism) but spills over into animosity toward outsiders (De Figueiredo and Elkins 2003, p. 175). Not everyone uses the term nationalism in this way. Some refer to all national

attachments as nationalism. I follow convention within political psychology and define nationalism as national chauvinism (Dekker et al. 2003). Nationalism is typically assessed by asking for agreement or disagreement with statements such as “other countries should try to make their government as much like ours as possible” or “the world would be a better place if other countries were more like ours” (Kosterman and Feshbach 1989).

A dislike or sense of superiority over other nations also colors views of immigrants within a nation. Nationalism is far more likely than patriotism to fracture national consensus because it is more divisive, leading to heightened xenophobia, negative views of immigrants, anti-Semitism, the derogation of foreigners, and classic racism (Ariely 2012; Blank and Schmidt 2003). Nationalism often surfaces as ethno-religious nationalism that is directed at both foreign nationals and internal ethnic and religious minorities. It narrowly construes who rightfully belongs to the nation, drawing restrictive national boundaries that exclude those who do not belong to the majority ethnic or religious group. It is associated with opposition to immigration policy and enhances perceived foreign threats. Far more so than patriotism, the effects of nationalism are consistent across national contexts. As I discuss below, nationalism may take similar form in different nations because it is grounded to some extent in stable personality characteristics such as authoritarianism (see also Feldman and Weber, Chapter 20, this volume). In contrast, the meaning of patriotism is more variable in part because it is an outcome of national norms that are linked in turn to a country’s particular culture and history.

1.2.1. *Ethnocultural Conceptions of the Nation; Christian Nationalism*

As noted earlier, researchers have identified ethnocultural nationalism as a specific form of nationalism (Citrin et al. 1990). Ethnocultural aspects of American identity include the need to believe in God, have American ancestry, or be Christian to be considered a “true American.” Such beliefs are less common than a civic understanding of American identity underscoring the divisive nature of such views (Citrin et al. 1990; Citrin et al. 2001; Citrin and Wright 2009). Ethnocultural nationalism can lead to exclusionary and hierarchical ethnic and racial distinctions in which non-White Americans (in the United States), Indian Muslims (in India), and Chinese Uighurs (in China) are regarded as of lower status than those of a nation’s dominant ethnic/racial or religious group (Bonikowski & Zhang 2020). As for other forms of nationalism, ethnocultural nationalism is linked to opposition to immigration and welfare assistance, especially in countries experiencing high levels of immigration (Wright et al., ; Wright and Reeskens 2013). In western Europe and in the United States, traditional measures of nationalism and ethnocultural nationalism measure the same concept (Huddy et al. 2021; Huddy and del Ponte 2021).

Other researchers have developed a related measure of Christian nationalism in the United States (Perry et al. 2021) that involves a perceived fusion of Christianity and the United States involving questions such as “The federal government should declare the United States a Christian nation.”

1.2.2. *Related Concepts: Blind Patriotism, Collective Narcissism, and Populism*

Schatz, Staub, and colleagues differentiate between two forms of patriotism: constructive and blind patriotism. *Blind patriotism* is defined as “an unwillingness both to criticize and

accept criticism” of the nation and is indexed by items such as “my country right or wrong” and the view that the country’s policies are morally correct (Schatz and Staub 1997, p. 231; Schatz et al. 1999). On the surface, blind patriotism captures an uncritical view of the nation not a sense of national superiority. Nonetheless, it is empirically linked to nationalism, ethnocentrism, and authoritarianism and is far closer to nationalism than patriotism in its political effects (Huddy and Khatib 2007; Schatz et al. 1999).

Golec de Zavala and colleagues’ (2009) concept of collective narcissism has similar ingredients (and consequences) to nationalism. Collective narcissism captures the view that other nations fail to recognize the uniqueness and greatness of one’s nation. This is tightly related to beliefs about national superiority, the hostile intentions of other nations, and a sensitivity to national threats that translate into negativity towards other nations. In that sense, the concept is closely aligned with that of nationalism because it is more focused on other nations than one’s own and linked to negative views of foreigners (Federico and Golec de Zavala 2018).

Some researchers regard populism as closely aligned with nationalism. Populism typically upholds the primacy of “the people” over the establishment and pits the good people against a corrupt and malevolent elite (Brubaker 2020; Mudde 2013; Mudde and Kaltwasser 2018). Populism and nationalism are often related empirically and can have similar political effects, especially when populism is aimed at immigrants, ethnic and cultural minorities, and foreigners. Some political parties and leaders classified as populist are also nationalist in outlook. As Bonikowski (2017) notes, however, populism is less an ideology than a style of governing, a political strategy, or a form of political rhetoric that champions ordinary people at the expense of cultural and political elites. In that sense, populism falls short as a fully blown ideology or belief system. Nationalism represents a more consistent belief system centered on national superiority and the minimization of foreign influence in national affairs (Bieber 2018; BruBaker 2020). It is thus important to distinguish a populist style of leadership from a leader’s pursuit of a nationalist ideology. From that standpoint, nationalism is a more clearly defined and readily measured concept than populism.

2. KEY THEORIES

2.1. Social Identity Theory

The psychology of national attachments can be analyzed through the lens of social identity theory, an extremely well-developed approach to the study of social identities (Tajfel and Turner 1979; Tajfel 1981). One of the theory’s major insights is that identities form readily, promote group cohesion, and are pervasive among members of any group, including a nation. From this perspective, national identities are essential to the smooth functioning of a nation. This conclusion is complicated, however, by two factors: (1) subgroup contestation over the meaning of patriotism and the specific beliefs and behaviors associated with a given national identity, and (2) variation in the degree to which national as opposed to potentially divisive partisan, ethnic, or other subnational identities are politically salient (Pérez and Vicuña, Chapter 25, this volume).

Social identity theory emphasizes the importance of symbolic concerns such as a group’s social standing as central to the development of group cohesion. There are two distinct

branches of social identity theory (SIT): the version developed by Tajfel (1981) and Tajfel and Turner (1979) known as social identity theory, and self-categorization theory (SCT), a cognitive elaboration of SIT (Turner et al. 1987). Both theories acknowledge the origins of social identity in cognitive and motivational factors, although SCT places greater emphasis on cognitive factors (Hogg, 1996, p. 67). Tajfel concluded that cognitive factors such as an awareness of belonging to a group could not solely explain intergroup relations and believed that motivational factors linked to the protection of group status were central to the emergence of intergroup bias. Both SIT and SCT place key emphasis on the need among group members “to differentiate their own groups positively from others to achieve a positive social identity” (Turner et al. 1987, p. 42).

The need for positive group differentiation leads to a mild form of ingroup bias, in which group identifiers exhibit a weak preference for ingroup over out-group members (Jackson and Smith 1999; Mummendey et al. 2001; Simon et al. 1995). In terms of national identity this means that individuals will prefer co-nationals to foreigners, although it does not automatically generate a dislike of outsiders. National identity is an attachment to the co-nationals with no necessary implication for how one feels toward outsiders (Huddy 2013; Mummendey et al. 2001; Sniderman et al. 2004). A liking for co-nationals among strong national identifiers means by implication that they will be more willing to help co-nationals than foreigners, more likely to conform to national norms, and more driven to defend the nation when it is threatened (Terry and Hogg 1996; Theiss-Morse 2009).

In addition, within social identity theory group solidarity rests on the development of a strong group identity (Huddy 2001). But not everyone identifies equally strongly with the nation (Pérez and Vicuña, Chapter 25, this volume). It is therefore imperative to measure gradations in the strength of national identity to fully understand its effects. It is well documented that strong group identifiers are more likely to conform to group norms (Terry and Hogg 1996). In the case of national identity, this means that strong national identifiers will be most likely to conform to prescriptive norms, such as voting in the United States or egalitarian behavior in Denmark and Sweden, and experience more positive emotions after conforming to them (Huddy and Khatib 2007; Christensen et al. 2004). For example, in several western European countries, a greater sense of national pride increases tax compliance, an indicator of national cooperation (Torgler and Schneider 2007).

Most citizens hold a subjective attachment to the nation in the form of an internalized national identity. Billig’s (1995) concept of banal nationalism helps to explain its ubiquity. From Billig’s perspective, references to the nation and its symbols, interests, and positive attributes underlie national discourse in ways that go unexamined but that powerfully shape citizens’ worldview. A national identity is associated with positive views of the nation but does not imply any specific meaning. It can be completely unrelated to a specific ideological outlook, for example (Citrin et al. 2001; Huddy and Khatib 2007), although national subgroups often compete for ownership over the national label and its symbols. When a consensual patriotic norm, such as voting or paying taxes, is made salient, strong national identifiers should be most inclined to enact the behavior.

2.2. Individual Differences: Personality Predispositions

From an individual difference perspective, holding a strongly patriotic or nationalistic outlook is linked to one’s underlying traits and personality (see Bakker, Chapter 2, this volume).

Authoritarianism has been seen as one of the most important precursors to the development of national attachments and is linked empirically to both patriotism and nationalism (Feldman and Weber, Chapter 20, this volume). Authoritarianism is defined as a preference for ingroup cohesion, social stability, and a heightened sensitivity to violations of group norms, and is associated with strong ingroup identification and conformity (Duckitt 2001; Feldman 2003). Osborne and colleagues (2017) delve into the personality-based origins of both patriotism and nationalism in a New Zealand panel study conducted over a three-year period. They found that authoritarianism measured at a prior point in time was linked to subsequent patriotism and nationalism. But they found far stronger effects of right-wing authoritarianism (RWA) on nationalism than patriotism over time. This is consistent with evidence from other studies of a sizeable association between authoritarianism and nationalism but not between authoritarianism and patriotism (Huddy and Khatib 2007; Huddy and Del Ponte 2021; Schatz and Staub 1997).

Osborne and colleagues (2017) also examine the effects of social dominance orientation (SDO) on national attachments. SDO is a predisposition tied to a belief in social hierarchy and a tough worldview (Duckitt 2001; Craig and Phillips, Chapter 23, this volume). SDO is linked to nationalism in their data but has no effect on patriotism. Osborne and colleagues ground their research in Duckitt's (2001) dual process model of ideology in which authoritarianism increases adherence to norms as a form of protection against threats to social cohesion, whereas SDO is associated with support for social hierarchies and a tough approach to the world. From Duckitt's perspective, these orientations are linked to early socialization and thus suggest that nationalism is at least to some degree a product of stable individual differences that vary little over time.

There is suggestive evidence that nationalism is constant over time at least in the aggregate. Huddy and Del Ponte (2019) examined levels of nationalism in 10 eastern and western European countries included in all three national identity modules of the ISSP (conducted between 1996 and 2014). There was no change over time in levels of nationalism across the ten countries. Nationalism is also linked in these data to educational attainment, another stable individual attribute. Better educated individuals tend to eschew nationalism contributing further to its stability (Huddy and Khatib 2007; Huddy et al. 2021). In contrast, education levels are less strongly associated with patriotism.

Researchers have examined the link between national attachments and other motivational and cognitive psychological predispositions. Golec de Zavala and colleagues (2019) view collective narcissism (equated here with nationalism) as a form of compensation for low personal self-esteem. In their research, high self-esteem is linked to patriotism, whereas low self-esteem is linked to collective narcissism, after controlling for the positive link between self-esteem and patriotism. From this perspective, someone who experiences low self-esteem adopts a sense of collective narcissism to bolster their sense of self. Collective narcissism fosters a sense of national superiority, increases the perceived hostility of other nations, and enhances a sensitivity to national threats all of which translates into negativity toward other nations. Golec de Zavala and colleagues argue that this process is distinct from authoritarian hostility toward foreign nations predicated on a desire for social cohesion and the protection of cultural values. Instead, collective narcissism arises as a response to foreign threats to the national image and status (Federico and Golec de Zavala 2018).

Finally, national attachments have also been traced to cognitive predispositions. Zmigrod et al. (2019) found that cognitive inflexibility (assessed objectively) predicts extremist attitudes, including a willingness to harm others, and sacrifice one's life for the group.

Across two samples ($N = 1,047$) drawn from the United Kingdom and the United States, cognitive inflexibility predicted endorsement of violent action undertaken to protect the national ingroup, which in turn predicted a willingness to sacrifice one's life for the nation.

In sum, nationalism but not patriotism appears to be an outgrowth of stable personality traits and abilities such as authoritarianism, SDO, low self-esteem, and levels of educational attainment.

2.3. Realistic and Cultural Threat

Many researchers view socio-economic threat and deprivation as precursors of nationalism. A common argument is that globalization and the presence of ethnically diverse immigrants threatens less skilled and less well-educated workers, leading them to endorse a more chauvinistic and exclusionary form of nationalism. Alternatively, some researchers point to threats emanating from immigrants who adopt different religious and cultural practices or hold differing values that threaten the majority's values and worldview. This position has been developed by Inglehart and Norris (Norris and Inglehart 2019). According to their cultural backlash hypothesis, publics have taken a nationalistic, populist turn because elite support of LGBTQ rights and racial justice has alienated those who view it as repudiation of their more "traditional" values.

Some researchers have combined the two approaches to argue that economic factors can act as antecedents to perceived cultural threats which then drive support for populism (linked to nationalism) (Rhodes-Purdy et al. 2021). From this perspective, economic crises generate negative emotions such as anxiety and anger which foster cultural resentment in turn. The cultural discontent generated by economic crises increases support for nationalist political figures and parties which place blame for economic woes on the increased influence of ethnic, minority, immigrant, and foreign forces.

2.4. Social Construction

There is widespread consensus that the nation is an "imagined community" (Anderson 1983) with an "invented tradition" (Hobsbawm and Ranger 1983). As noted by Mylonas and Tudor (2021) "States today are self-conscious actors in the process of nation building, often systematically attempting to make national attachments primary" (p. 117). From this constructivist perspective, national leaders work to create cohesion among people who may not share the same ancestral ethnicity, customs, or heritage. Nations come to take on meaning through the reinforcement of specific practices, the creation and amplification of national myths, reinforcement of a common religion, enforcement of a national language, and a selective historical narrative (Hopkins, Chapter 9, this volume). Such views of the nation are transmitted via education, social norms, laws and institutions, and everyday discourse (Billig 1995).

The constructivist approach is central to an understanding of national norms that dictate beliefs about a country's founding, its patriotic practices such as civic behaviors, and the kinds of beliefs and behaviors adopted by a typical citizen. Social constructivism—the notion that concepts derive their meaning through social processes—is implicit within

social identity and self-categorization theory, which stresses the ease with which social groups and social identities form and develop meaning for members of arbitrarily designated groups (Huddy 2001; Reicher 2004). From a social constructivist perspective, it is difficult to understand the consequences of group identification without understanding its subjective meaning to group members (Billig 1995). This is especially important for national identities, which often have contested meaning. Members of diverse subgroups can attach a different meaning to national identity, depending on their race or ethnicity or the region of the country in which they live (Reicher and Hopkins 2000; Schildkraut 2011).

The meaning of national identity is also likely to have its most profound effect among the strongest national identifiers, helping to explain the link between national identity and patriotism. In Sindic and Reicher's (2009) research, strongly identified Scots who viewed Scotland as dominated by the English, felt their identity was undermined by a union with Britain, and saw the two identities as incompatible were far more likely than others to support Scottish nationalism and political independence from Britain. But in the absence of a strong Scottish national identity, these beliefs had far less political impact. Political parties can also shape the meaning of national identity. In the 1992 Scottish elections, the Scottish National Party, which favored independent statehood emphasized that Scottish identity, was incompatible with English identity (Reicher and Hopkins 2001). In contrast, the conservatives, who supported continued ties with Britain, emphasized Britishness and the commonalities between the Scots and English while downplaying Scottish distinctiveness.

2.5. Framing, Rhetoric, and Elite Influence Theory

Unlike the other approaches discussed here, framing theories are focused more on the activation of national attachments than on their origins or nature. In that sense, the approach is compatible with the personality approach to nationalism, discussed earlier. Scholars working within this framing perspective take as a given the existence of stable levels of national attachments and study the factors that heighten their political salience (Beiber 2018). Within this approach, exogenous factors such as massive economic, cultural, or political change, and/or subjectively perceived social marginalization and status threat fuel the rise of nationalist rhetoric (Bieber 2018; Bonikowski 2017). This in turn fosters the emergence of nationalistic political parties and candidates that attract those predisposed to support nationalism (Huddy et al. 2021). As Bonikowski (2017) notes, nationalistic attitudes have remained stable even as support for nationalistic political parties has increased. Party success is thus more a function of growing support from nationalistic citizens than rising levels of nationalism. This leaves unclear, however, why nationalistic political parties have emerged at roughly the same point in time across diverse countries to attract citizens with pre-existing nationalistic leanings. It is possible that nationalistic political parties emerge as a reaction to common international trends such as a global recession or migration precipitated by climate change.

Elite influence theory provides the foundation for predictions concerning framing effects. From this perspective, public opinion is a top-down phenomenon driven largely by powerful partisan messages that have their greatest effect among the most politically attentive and knowledgeable (Kalmoe 2020). Zaller (1992, 2012) posits three factors as necessary for successful elite influence. First, the news media needs to cover an argument or

message with some frequency (*supply*); second, a person needs to be exposed to this information (*exposure*); third, a message to which someone is exposed needs to have resonance for them leading to its acceptance or rejection (*acceptance*). A nationalistic party or political leader who promotes a nationalistic agenda can increase the link between nationalism and opposition to free trade, immigration, and involvement in supranational entities such as the EU among members of the public. This rhetoric has special resonance among the most highly nationalistic residents who are the first to shift their political views in tandem with agreeable frames (Lenz 2013; Page and Shapiro 1992; Zaller 1992). If a message conveying nationalistic opposition to the EU is absent from the news it is unlikely to influence public opinion, but if a nationalistic message is ubiquitous and meets with broad acceptance it will be persuasive. Within this model, elites do not increase levels of nationalism—they increase its political salience and relevance.

3. THE MEASUREMENT OF NATIONAL ATTACHMENTS

In analyzing the link between globalization and national identity, Ariely (2012) notes that “little agreement exists among scholars regarding the measurement of national identity” (p. 467). That is an understatement. The International Social Science Programme’s (ISSP) national identity modules provide one of the richest sources of data on national attachments. The module has been included in three distinct ISSP surveys (conducted in numerous countries in 1996, 2004, and 2014). The data set is widely used in political science and sociology, but items are not used consistently to define key concepts. Some researchers pick one, some several, and still others all relevant items to measure a specific concept. Worse, some researchers combine items measuring different concepts in a single scale. This lack of measurement consistency poses an obvious hurdle to the accumulation of knowledge on the determinants, nature, and political consequences of national attachments.

3.1. National Identity

In psychology, social identities are measured with multi-item scales that reflect a mix of cognitive factors, such as the acknowledgment that one belongs to a nation or use of the term “we” for co-nationals, and affective factors, such as the subjective importance of national belonging (Huddy and Khatib 2007; Mummendey et al. 2001; Sidanius et al. 1997). Citrin et al. (2001) draw on similar items to tap the strength of American identity among respondents in the 1996 General Social Survey (GSS). The following are common items: “How important is being American to you” and “how close do you feel to [COUNTRY]” (see also Sniderman et al.’s 2004 use of Crocker and Luhtanen’s collective self-esteem scale). These items do not touch on the meaning of national identity and avoid contentious behaviors, such as standing for the national anthem, or divisive beliefs such as a dislike of foreigners. Some researchers take another tack and attempt to measure the primacy of national versus an international or supranational identity (Hooghe and Marks 2004). In the ISSP data,

national identity is measured with a single item asking how close the respondent feels to their country (Huddy and del Ponte 2019; see Table 21.1).

3.2. Patriotism

Group identity is typically accompanied by a sense of ingroup bias, defined as somewhat more positive ratings of one's own than other nations and nationals. This ingroup bias is often defined as patriotism, a positive feeling or a sense of pride in a country and its achievements. In the ISSP national identity module data (Table 21.1), nationals are asked

Table 21.1 National Identity, Nationalism, and Patriotism Items (ISSP National Identity Module)

NATIONAL IDENTITY

How close do you feel to [COUNTRY]

NATIONALISM

Ethnocultural (. . . to be a TRUE COUNTRY NATIONAL)

How important is it to have been born in [COUNTRY]?

How important is it to have [COUNTRY NATIONALITY] citizenship?

How important is it to have lived in [COUNTRY] for most of one's life?

How important is it to speak [COUNTRY LANGUAGE]?

How important is it to have [COUNTRY NATIONALITY] ancestry?

How important is it to be a [religion]?

Nationalism

I would rather be a citizen of [COUNTRY] than of any other country in the world.

There are some things about [COUNTRY] that make me feel ashamed of [COUNTRY].*

The world would be a better place if people from other countries were more like the [COUNTRY]

Generally speaking, [COUNTRY] is a better country than most other countries.

People should support their country even if the country is in the wrong.

PATRIOTISM

Civic Patriotism (. . . to be a TRUE COUNTRY NATIONAL)

How important is it to respect [COUNTRY]'s political institutions?

How important is it to feel [COUNTRY NATIONALITY]?

National Pride

When my country does well in international sports, it makes me proud to be [COUNTRY NATIONALITY].

How proud are you of [COUNTRY] in the way democracy works?

How proud are you of [COUNTRY]'s political influence in the world?

How proud are you of [COUNTRY]'s economic achievements?

How proud are you of [COUNTRY]'s social security system?

How proud are you of [COUNTRY]'s scientific and technological achievements?

How proud are you of [COUNTRY]'s achievements in sports?

How proud are you of [COUNTRY]'s achievements in the arts and literature?

How proud are you of [COUNTRY]'s armed forces?

How proud are you of [COUNTRY]'s history?

How proud are you of [COUNTRY]'s fair and equal treatment of all groups in society?

How proud are you of being [COUNTRY NATIONALITY]?

how proud they feel as a national of their country and of a long list of aspects of their nation's history, culture, and institutions. The ISSP pride items are not always fully exploited to measure patriotism. Some researchers pick a single item to measure national pride (Ariely 2012), others combine several (Davidov 2009), and still others use all pride measures (de Figueiredo and Elkins 2003). Other patriotism scales tap positive feelings about specific patriotic symbols such as the national anthem and flag (Peffley and Hurwitz). Some researchers combine national identity and pride items into a single measure. This latter strategy was used by Johnston et al. (2010) to measure Canadian identity, combining the rated importance of being Canadian, a sense of belonging to the Canadian community, pride in being Canadian, and positive feelings for the country.

3.2.1. *Civic Patriotism*

As noted above, there is a widely discussed distinction across and increasingly within nations between an *ethnocultural* view of national belonging (e.g., based on a common ethnic heritage) and *civic patriotism*, linked to a common national purpose and shared goals (Citrin et al. 1990; Li and Brewer 2004; Smith 1988). To assess these views, survey respondents are asked to rate various attributes as indicative of a true or good citizen. Civic patriotism is measured with items that equate good citizenship with following the laws, respecting the country's institutions, voting, and feeling like a national (see Table 21.1). In the United States, civic patriotism is more common than an ethnocultural understanding of the nation. When asked why they rate themselves as a "particularly good," "good," "ordinary," or "not so good citizen" and what they could do to become a better citizen, most Americans mention voting (Conover et al. 2004; see also Devos and Banaji 2005).

One of the difficulties in developing distinct measures of ethnic and civic understandings of American identity has been respondents' tendency to rate all aspects of national identity as equally important. Some researchers working outside the United States document distinct ethnocultural national and civic factors in analyses of questions concerning what constitutes a good citizen (Reeskens and Hooghe 2010; Helbling et al. 2016). But the strong empirical link among all items has made it difficult to create two competing scales in some national contexts, a problem that has bedeviled research in this area for some time. Miller and Ali (2014) get around this problem by subtracting scores on the civic and ethnic conception measures to obtain a difference score. Wright and Citrin (2012) solve this problem by switching from questions that ask people to rate the importance of various attributes to ranking them. This solution leads to a clearer distinction between those who prefer nativist ethnocultural characteristics and those who prefer civic attributes, revealing the association between ethnocultural aspects of identity and increased opposition to immigration.

3.2.2. *Constructive Patriotism*

Constructive patriotism was initially measured by Schatz and Staub (1997) by items such as "I oppose some U. S. policies because I care about my country and want to improve it" and "I express my love for America by supporting efforts at positive change" (Schatz and Staub 1997). Others have measured constructive patriotism differently using three items from the ISSP: pride in the country's democracy, pride in its social security system, and the fair and

equal treatment of all groups in society, although this blurs the distinction between civic and constructive patriotism (Davidov 2009; Meitinger 2017). There is a potential confound between love of country and political engagement in the original constructive patriotism scale and it is not surprising that Schatz and colleagues find a clear link between political involvement and constructive patriotism (Schatz et al. 1999; Rothi et al. 2005). But it also raises questions about the nature of the scale. Is constructive patriotism primarily a measure of patriotism? Or of political interest and involvement?

3.3. Nationalism

Nationalism has traditionally been measured with scale items tapping its chauvinistic side such as agreement with the statement that “other countries should try to make their government as much like ours as possible” (Kosterman and Feshbach 1989). The ISSP nationalism battery includes five-scale items that tap a sense of national superiority, including items such as “The world would be a better place if people from other countries were more like the [COUNTRY NATIONALITY]. And Generally speaking, [COUNTRY] is a better country than most other countries” (Table 21.1). As for patriotism, there is a lack of consistency in how these items are used, however. Researchers often choose a subset of the 5 items to assess nationalism (Ariely 2012; Davidov 2009; Sumino 2021). Other national elections surveys, such as the 2016 and 2020 American National Election Survey (ANES), include just one item to measure nationalism: “The world would be a better place if people from other countries were more like Americans.”

3.3.1. *Ethnocultural Nationalism*

As noted, an ethnocultural conception of the nation is assessed by asking respondents about the desired attitudes and behaviors of “true” or “good” citizens (Bonikowski 2017). In the United States, Citrin and colleagues have measured ethnocultural nationalism in the United States as the view that a true American is Christian and born in the country (Citrin et al. 1990, 2001; Citrin and Wright 2009; Smith 1997). The ISSP series includes questions about majority ethnic ancestry, majority religion, speaking the majority language, having been born in the country, having lived most of one’s life there, and holding citizenship. These constitute aspects of an ethnocultural understanding of the nation.

3.3.2. *Combined Nationalism Scale*

Huddy and colleagues (2021; Huddy and del Ponte 2021) analyzed the structure of the ISSP national attachment measures in western Europe and the United States and identify two factors—nationalism and patriotism—that capture the measurement structure of national attachment items. The nationalism factor is comprised of items tapping an ethnonationalism conception of the nation plus standard nationalism scale items (see Table 21.1). This single factor indicates that nationalism is a unitary concept. The two-factor structure shows measurement invariance across western European nations and between Blacks and Whites in the United States (Huddy et al. 2021; Huddy and del Ponte 2021). Moreover, ethnonationalism

and traditional scale measures of national chauvinism have very similar effects reinforcing their conceptual overlap (Citrin et al. 1990; Citrin et al. 2001; Hochman et al. 2016; Lindstam et al. 2019; Schildkraut 2011; Wong 2010).

3.3.3. *Alternative Measures of Nationalism*

The collective narcissism scale captures a slightly different aspect of nationalism, emphasizing the failure of other nations to recognize the uniqueness and greatness of one's nation. Sample items include "Not many seem to fully understand the importance of the United States" (Federico and Golec de Zavala 2018). But the collective narcissism scale also includes items that overlap with that of traditional nationalism measures such as "If my nation had a major say in the world, the world would be a better place" (Golec de Zavala et al. 2009). The original scale has nine items, although shorter versions also exist (Federico and Golec de Zavala 2018).

3.4. Scales vs Typology

Rather than array people on multiple, correlated scales, some researchers have developed typologies of national attachments that sort people into distinct groups. Bonikowski and Di Maggio (2016) divide Americans into four latent classes based on their responses to items assessing patriotism, nationalism, and national identity in the 2004 ISSP/GSS national identity module. The four groups are (1) ardent nationalists who feel close to America, endorse numerous attributes as central to being a true American, are very proud of the nation, and are high on chauvinism; (2) restrictive nationalists who hold an exclusive view of what it means to be Americans but are not high in national pride; (3) creedal Americans who feel proud of the national but place few restrictions on what it means to be a true American; and (4) the disengaged who express low levels of pride and a weak sense of national identity. This typology complements the distinction between patriotism and nationalism. Some Americans are high in both patriotism and nationalism (ardent), and some are low on both scales (disengaged), consistent with a moderately high positive correlation between the two scales in survey data. Other Americans are higher on one than the other (restrictive and creedal). Stronger endorsement of the nationalism items (among the ardent and restrictive) is linked to isolationism and a negative view of immigrants. This finding underscores the political value of the nationalism scale; it also challenges the need for a typology that fails to draw a clean distinction between patriotism and nationalism.

Bonikowski and de Maggio's (2016) typology has been replicated in a much larger numbers of countries (Soehl and Karim 2021). It also has some parallel in Satherley and colleagues' (2019) latent class analysis in which New Zealanders are divided into two distinct groups: a subgroup of people who endorse patriotism but not nationalism (11%) and those who are both highly nationalistic and patriotic (33%). The researchers identify other classes, but they are less clear-cut because they reflect middling or lower levels of both patriotism and nationalism. Once again, groups that endorse nationalism have less-positive ratings of immigrants, underscoring the distinct political relevance of a nationalism scale. On average, there is greater political benefit to the identification of nationalism than the

sorting of people into distinct typologies that reflect some mix of high and low scores on nationalism and patriotism, although both the scale and typology approaches have merit.

Other researchers have employed a Q-sort methodology to place Americans into various typologies. Sullivan and colleagues (1992) divide Americans into a group of nationalists and four types of patriots. Patriots included Americans who embrace national symbols, those who reject them in favor of patriotic political activism (akin to constructive patriotism), those who ground patriotism in protection of the environment, and those who equate patriotism with capitalism. Hanson and O'Dwyer (2019) conducted a Q-sort that divided Americans into two distinct groups: political liberals who prioritized an active and critical form of political involvement in the nation, and conservatives who prioritized equality of opportunity, national symbols, and national pride. Part of the difficulty with the Q-sort technique, however, is that typologies are often based on small samples and depend heavily on the items included in the sort.

3.5. Next Steps

The measurement of national attachments remains confusing and fragmented. A more systematic approach is needed to bring coherence to this area of research. There is promise in approaches that measure concepts with multi-item scales that have higher predictive validity than a single item (Huddy et al. 2021). There is also virtue in using standard concepts and measures, perhaps even including multiple such measures in a single study, to allow for a better assessment of the validity of existing scales. Data contained in the ISSP national identity modules provide this kind of rich measurement resource and deserve to be used more widely than now by political psychologists. All in all, research on national attachments begs for more systematic attention to issues of measurement. Despite measurement inconsistency, however, patriotism and nationalism have distinct political effects, as I discuss below.

4. THE POLITICAL CONSEQUENCES OF PATRIOTISM AND NATIONALISM

4.1. National Identity, Patriotism, and Social Cohesion

4.1.1. *Social Trust and Assistance*

There is empirical support for the claim that national identity works as national glue. Several studies find an increased link between national identity, trust of co-nationals, increased compliance with national norms, and decreased ethnic and partisan divisiveness, although not all studies arrive at this conclusion. Supportive evidence comes from several different strands of research.

First consider evidence that priming national identity increases trust and social cohesion. Blouin and Mukand (2019) found that exposure to government propaganda

emphasizing national unity decreased the salience of ethnicity, increased interethnic trust, and strengthened the willingness to interact face-to-face with non-co-ethnics in Rwanda. Depetris-Chauvin and colleagues (2020) report that a national football team's victory boosted trust in other ethnicities and reduced intrastate violence in sub-Saharan Africa. Robinson (2016) reports that a strong national identity in Malawi led to increased trust of co-nationals in a trust game regardless of shared ethnicity. In this research, priming the national flag also increased trust in co-nationals among those who were less strongly identified with the nation. A strong national identity is associated with enhanced assistance to co-nationals in need (Johnston et al. 2010; Theiss-Morse 2009). Maki et al. (2019) found that those with a stronger national identity were more likely to assist co-nationals affected by a major earthquake in Chile in 2010. In addition, a strong national identity fuels the adoption of protective public health behaviors in a broad range of countries (van Bavel et al., 2022; Cárdenas et al. 2021; Chan et al. 2021).

In a similar vein, several experimental and non-experimental studies document a link between strong national identity and support for policies that benefit immigrants and co-nationals of diverse racial backgrounds (Ariely 2012; Collingwood et al. 2018; Huddy and del Ponte 2019; Osborne et al. 2019; Satherley et al. 2019; Soroka et al. 2017). For example, White Americans are more supportive of spending on minority education when their national identity is made salient but are less supportive of the same program when their racial identity is salient (Transue 2007). Charnysh et al. (2015) found that priming the nation among Hindus by exposing them to a map of the country colored by the national flag increased support for co-nationals across divisive religious lines. In this study, Hindus gave more to Hindu than Muslim fire victims without a national prime but gave equally when the map and flag were made salient. The 9/11 terrorist attacks may have had a similar effect on White Americans. In one study, experimental exposure to information about the events of 9/11 heightened American identity and increased support for multiculturalism policies (Davies, Steele, and Markus, 2008).

Civic patriotism has similar effects. Those who rank highly the civic aspects of American identity are more supportive of increased immigration and less supportive of policies that favor English-speaking immigrants (Citrin and Wright 2009). They are also more inclined than others to think that volunteering, donating money to charity, and serving in the military is an obligation they owe to other Americans (Schildkraut 2011).

4.1.2. *Civic Engagement*

In the United States, American identity is associated with civic behaviors such as voting, greater political attention, and higher levels of political knowledge (Huddy and Khatib 2007). Social identity theory predicts greater adherence to group norms among strong group identifiers, translating in the case of American identity into greater civic involvement among strong national identifiers. Those high in civic patriotism are more inclined to think that volunteering, donating money to charity, and serving in the military is an obligation they owe to other Americans (Citrin and Wright 2009; Lindstam et al. 2019; Schildkraut 2011).

The overlap between national and ethnic or racial identities among members of minority groups has particular importance for political engagement and citizenship. Simon and

colleagues report that a dual identity as a Russian-German or Turkish-German, indicated by statements such as “Sometimes I feel more as a German and sometimes more as a Turk,” enhances political activity and support of group-related political issues among immigrants in Germany (Simon and Grabow 2010; Simon and Ruhs 2008). These dual identities exhibit attributes of Brewer and Roccas’ complex identities in which no one of the two identities dominates. In the absence of a dual identity, ethnic identity does not foster electoral engagement on behalf of the minority group. This points to the essential role of national identity in fostering civic engagement.

4.1.3. *Limits to Patriotic National Cohesion*

The cohesion effected by strong national identity and patriotism is readily fractured, however, placing clear limits on national unity. In democracies, co-nationals are often divided along partisan and ideological lines. Kam and Ramos (2008) underscore the tension between partisan conflict and national unity, demonstrating the degree to which such outcomes are conditioned by the relative salience of one or another identity. In their research, national identity shapes presidential approval in periods of national threat but partisan identity has greater effect on presidential approval in “normal” political times. In a similar vein, Levendusky (2018) conducted an experimental study in which he primed American identity, increasing the sense that outpartisans were fellow Americans. This modestly reduced partisan affective polarization and improved positive ratings and trait judgments of opposing partisans. In a politically polarized nation, there are obvious limits on the ability of national identity to effect national solidarity and cohesion. Chan (2021) found that national identity predicted the enactment of protective public health behaviors during the COVID pandemic in both China and the United States. But this link was complicated in the United States among conservatives who strongly identified with the Trump administration and were slower to adopt preventive behaviors of benefit to co-nationals.

Johnston and colleagues (2010) note other limits to the cohesive effects of national identity. They argue that national identity will increase support for policies seen as foundational or tightly linked to the nation, such as Social Security or Medicare in the United States. They demonstrate the link between national identity and support for national health care in Canada, a point of pride within the country, but found less support for the old-age pension and anti-poverty programs, which are not regarded as foundational aspects of the Canadian welfare system. The authors speculate on the importance of the historical development of a country’s welfare state to explain why some policies are tightly tied to national identity and others are not. In countries such as Sweden, national identity is likely to be tightly linked to support for the entire welfare state whereas that is far less likely to be true in the United States or Canada.

Internal threats may also undermine the cohesive effects of national identity. Indeed, strong national identifiers may experience threats from members of a minority group as more of a national affront and consequently draw more exclusive national boundaries in the face of such threats. For example, Sniderman, Hagendoorn, and Prior (2004) found that a strong national Dutch identity was associated with greater perceived threats to Dutch culture and that priming national identity increased opposition to immigration, especially among those with low prior levels of perceived cultural threat. Other studies

report similar findings in which cultural threat interacts with national identity to increase discrimination toward co-nationals of different racial or ethnic backgrounds (Falomir-Pichastor et al. 2009). These findings might reflect the political arousal of chauvinistic nationalism but could also underscore the conditions under which patriotic national unity can be fractured.

In sum, the cohesive effects of national identity and patriotism are fragile. They are eroded by divisive partisan conflicts. They are limited to specific aspects of social welfare policy linked to a country's history, complicating any automatic link between national identity and support for a specific national policy (Miller and Ali 2014). As Theiss-Morse (2009) finds, strong American identifiers will extend assistance to other Americans, but this assistance does not extend to the beneficiaries of social welfare programs. Collingwood and colleagues (2018) provide an interesting descriptive example of the conditions under which national identity drives policy support. They argue that President Trump's travel ban against Muslims in early 2016 was portrayed by the news media as anti-American, resulting in increased opposition to the ban among strong American identifiers. In the presence of political divisions or in the absence of strong political norms linking a policy to the nation, however, national identity does not automatically drive support for policies that benefit co-nationals.

4.1.4. National Identity, Patriotism, and International Cooperation

National identity and patriotism also foster support for international cooperation and supranational entities. In western Europe, a strong national identity is associated with greater trust in national institutions that are, in turn, embedded within the EU. In such countries, a strong national identity increases EU support (Anderson 1998; Hobolt and deVries 2016; although for contrary findings see Carey 2002). But this, too, is a contingent process. Strong national identifiers are more reactive than others to national threats, shifting support or neutrality toward a threatening nation into opposition, anger, and aggression.

Researchers studying a range of different groups find that strong group identifiers react more angrily than others to group threat (Mason, Chapter 24, this volume; Musgrove and McGarty 2008; Rydell et al. 2008; van Zomeren et al. 2008). When it comes to national identity, strong American patriots reacted with greater anger toward terrorists in the lead up to the Iraq war, heightening their support for war (Feldman et al. 2015; Huddy et al. 2007). Strong American identifiers also responded with greater anger to an insulting message about the United States and Americans written by a foreigner (Rydell et al. 2008). Fischer et al. (2010) made salient British subjects' national or gender identity and then exposed them to photos of the July 7, 2005, London bombings. Subjects whose British identity was made salient were more likely to report feeling aggression and expressed greater support for the war on terror than those for whom gender identity was made salient.

4.2. Nationalism and National Divisions

National identity and patriotism can enhance national solidarity, increase trust, and promote support for national policies. But their effects vary with context, circumstances, and

the meaning of national identity. In contrast, the political effects of nationalism are far more uniform and predictable.

4.2.1. *Nationalism Undermines International Cooperation*

Nationalism typically has ethnocentric effects that undermine international cooperation. It diminishes support for supranational political entities, promotes opposition to global trade, and fosters opposition to immigration. Indeed, highly nationalistic Americans will only support free trade if it yields outsized monetary gains to their nation (Mutz 2021). In the ISSP European data, nationalism consistently boosts support for protectionism and anti-immigration policies across countries (Huddy and Del Ponte 2019). Holding an exclusive national identity distinct from Europe diminishes support for the EU, and, while this is not a measure of nationalism, the two have very similar effects (Marks and Hooghe 2003). Both an exclusive national identity and nationalism increase support for nationalist policies and political parties (Dunn 2015; Kentmen-Cin and Erisen 2017; Mayda and Rodrik 2005).¹ Scotto and colleagues (2018) show greater support for the Leave side in the UK Brexit vote among nationalists and greater support for Remain among those classified as globalists. Domm (2004) finds that nationalism has negative effects on the belief that one's nation benefits from EU membership.

4.2.2. *Nationalism, Exclusionary Domestic Policies*

Nationalism also influences domestic policy views. Individuals who endorse an ethnocultural view of American identity, equated here with nationalism, are more likely to oppose policies designed to benefit new immigrants, view negatively the impact of immigration, support English-only vote ballots, endorse ethnic profiling of Arab Americans, and generally support restrictions on civil liberties for non-citizens (Citrin et al. 1990; Citrin et al. 2001; Huynh et al. 2015; Schildkraut 2011; Sengupta et al. 2019; Wong 2010). In general, nationalism is linked to heightened xenophobia, anti-immigrant attitudes, anti-Semitism, the derogation of foreigners, classic racism, and a higher social dominance orientation (Ariely 2012; Blank and Schmidt 2003; de Figueiredo and Elkins 2003; Pehrson et al. 2009; Sidanius et al. 1997; Wagner et al. 2012).

Theiss-Morse (2009) demonstrates that ethnocultural nationalism places clear boundaries on who qualifies as an American. This in turn limits support for government policies that benefit members of diverse ethnic and racial minority groups. In that sense, nationalism places clear limits on support for spending on policies that benefit members of minority groups, including social welfare, education, and the improvement of urban areas. In this way, ethnocultural nationalism defines who constitutes “we” and places boundaries on ingroup cooperation.

4.2.3. *Political Disengagement*

One of the puzzling aspects of nationalism is its link to political disengagement. Unlike national identity or civic patriotism which are associated with higher levels of political engagement, strong nationalists tend to voter at lower levels than others and express less

interest in politics (Huddy and Khatib 2007). Consider uncritical patriotism. Schatz and colleagues (1999) find *lower* not higher levels of political involvement and interest among uncritical patriots. They do not provide a clear theoretical basis for this observed relationship, but they demonstrate a link between authoritarianism and uncritical patriotism which provides a plausible explanation. Authoritarians typically exhibit lower levels of political information, interest, and involvement that can be traced to their reduced scores on openness to experience and lesser interest in exposure to new information (Altmeyer 1996; Feather et al. 2001; Lavine et al. 2005). Moreover, a general political passivity among authoritarians is consistent with one of their defining attributes—a greater deference to authority figures (Altmeyer 1998). This helps to explain lower levels of political involvement and interest among strong nationalists due, in part, to their greater authoritarianism. This trend may be upended, however, when strongly nationalistic politicians, such as Donald Trump, or nationalistic policies, such as Brexit, are on the ballot. Nationalistic political figures and policies can attract voters high in nationalism, overturning their habitual disinclination to participate in democratic politics. This is an important area for future research investigation.

4.3. Support for Nationalist Political Parties and Leaders

There has been an obvious rise in nationalistic political parties and leaders in Europe, the United States, and elsewhere in recent years. Prime examples of nationalistic political parties and their leaders in Europe include the National Rally in France (Marine Le Pen), the Italian Northern League (Matteo Salvini), Law and Justice in Poland (Andrzej Duda), and Fidesz in Hungary (Viktor Orban). The US Republican Party took a nationalistic turn that was most obvious following the election of Donald Trump in 2016, but had been present since the terror attacks of September 11, in tandem with growing Republican opposition to immigration (Bartels 2018). Nationalistic parties and leaders have arisen elsewhere in the world including Turkey (Recep Tayyip Erdogan and the Justice and Development Party), India (Narendra Modi and the BJP), the Philippines (Rodrigo Duterte and PDP-Laban), and Brazil (Jair Bolsonaro). Leaders of such parties combine an overt love of country with support for nationalistic economic and social policies including skepticism of supranational forces such as the EU and the UN.

Perhaps unsurprisingly, support for nationalistic leaders and political parties is grounded in nationalism not patriotism. Donald Trump attracted support from White Americans holding anti-immigration and nationalistic views in the 2016 presidential election (Reny et al. 2020; Mutz 2018), continuing a decade-long trend in nationalistic White support for Republican candidates (Huddy and del Ponte 2021). Other forms of nationalism have also been tied to support for nationalist parties. Chichoka and Cislak (2020) show that collective narcissism is linked to support for populist parties. There is also evidence that collective narcissism had powerful influence on positive ratings and electoral support for Trump in the 2016 election (Federico and Golec de Zavala 2016). Dunn (2015) documents strong nationalist support for right-wing populist parties in Western Europe.

4.3.1. *The Political Activation of Nationalism*

If nationalism is linked to stable underlying aspects of personality and early socialization, how can we explain variation over time in the political potency of nationalism? The existence

of a nationalist political party and broad dissemination of its agenda help to explain this dynamic. Even at low levels of electoral success nationalist political parties receive considerable media attention (Bischof and Senniger 2018). A neo-nationalist party with a larger vote share typically receives even greater media attention than one with weaker electoral outcomes (Vliegthart et al. 2012). This points to the critical role of media exposure in disseminating the ideas and policy platform of a nationalistic party and thus increasing awareness of its agenda, consistent with the dynamics of an elite influence theory of public opinion.

According to Hooghe and Marks (2004), the divisive political rhetoric found among the leaders of Euroskeptical political parties can enhance the negative effects of an exclusive national identity on EU support. More broadly, the mere presence of a neo-nationalist party in a country can create a megaphone for nationalistic citizens and foster a climate of intolerance toward outgroups. A study by Van Assche and colleagues (2017) provides an example of this process. Using data from the European Social Survey (ESS) and the World Values Survey (WVS), the authors found that a right-wing climate in a country or a sub-national region was associated with more negative outgroup attitudes among citizens regardless of their personal ideology. The authors did not test whether this effect was confined to nationalistic citizens but that is a distinct possibility. Using Eurobarometer data from twelve European countries, Semyonov et al. (2006) found that anti-immigrant attitudes were more pronounced across the general population precisely in countries where extreme right-wing parties enjoy greatest support.

Huddy and colleagues (2021) find additional support for elite influence theory in analysis of ISSP data from western Europe. In their data, nationalistic opposition to the EU is more common in countries with a neo-nationalist party and far less common in countries that lack such a political party. In their research, levels of nationalism do not map in any obvious way onto countries that did and did not have a neo-nationalist party, ruling out the notion that countries with high levels of nationalism are more likely to have a nationalist political party. Denmark had one of the lowest levels of nationalism in the ISSP data yet had a nationalist party, whereas Ireland had one of the highest levels of nationalism and lacked a party. Moreover, in Huddy et al.'s research (2021), the best-educated nationalists were most opposed to the EU. This may seem counterintuitive but is consistent with the expectation that elite influence has its greatest influence on those exposed to a message, something that is more common among better-educated citizens who are more politically attentive than those with lower levels of education (Zaller 1992).

There is also evidence that the effects of a nationalist party are further enhanced by the actions of mainstream political parties which may weaken their support for immigration when facing nationalist opposition (Abou-Chadi and Krause 2020). In sum, the supply of nationalist rhetoric can enhance the political effects of nationalism. This finding is consistent with other research showing that political rhetoric is needed to translate societal trends, such as an increase in the immigrant population, into policy attitudes (Bruter 2003; Hopkins 2011).

4.4. Sharply Contrasting Effects of Patriotism and Nationalism

Patriotism and nationalism can have sharply contrasting political effects, especially on matters linked to immigration, the treatment of foreigners, and views of internal ethnic

minorities. When it comes to immigration, patriotism promotes national unity and increases support for immigration and globalization whereas nationalism fosters divisive opposition to foreigners and domestic immigrants in the United States and western Europe (Huddy and Khatib 2007; Huddy et al. 2021). Carter and Perez (2016) find unifying effects of pride and fracturing effects of national chauvinism in a survey of Black and White Americans. Among White and Black Americans, nationalism decreased positive ratings of African, Asian, and Latino immigrants; it also decreased Black ratings of White immigrants. In contrast, national pride boosted Blacks' ratings of African, Asian, Latino, and White immigrants although had more limited effects among Whites (confined to more positive ratings of Asian immigrants). In Ariely's (2012) analysis of 2003 ISSP data, pride in the country's democracy, social security, and treatment of groups similarly led to more positive views of immigration whereas national chauvinism led to more negative assessments. Domm (2004) also shows that nationalism has negative and patriotism positive effects on the belief that one's nation benefits from EU membership.

The contrasting effects of nationalism and patriotism on immigration and related matters raises two critical considerations. First, it is important to note that nationalism and patriotism are typically positively correlated. This means that the inclusion of one measure without the other could mask evidence of their complex positive and negative effects on political attitudes such as support for increased immigration. Second, the positive correlation between patriotism and nationalism but their contrasting political effects underscores the importance of each national attachment's salience within national politics. If national leaders are unified in their support of a particular policy, strong national identifiers and patriots are likely to fall in line, reducing the salience of nationalistic opposition. Conversely, politicians who oppose a policy on nationalistic grounds will increase policy opposition among strong nationalists.

Finally, I need to underscore the differing political effects of distinct forms of national attachments in the United States and elsewhere. Despite their positive association, nationalism and patriotism have opposing political effects. In the United States, nationalism promotes opposition to immigration, increases support for trade protectionism, and boosts White support for the Republican Party over time, whereas patriotism promotes support for immigration and increases opposition to trade protectionism across racial lines. We find similar trends in western Europe, where strong nationalism fuels opposition to immigration, free trade policies, and the EU, and promotes electoral support for populist parties whereas patriotism strengthens support for the same policies and the EU (Huddy et al. 2021).

5. MAJORITY AND MINORITY STATUS

5.1. Levels of National Attachment and Political Effects

Nation states are often formed by core ethnic groups, whose language and culture come to dominate state practices. This results in somewhat higher levels of national attachment among members of founding majority than minority ethnic groups within a nation, although this also varies by nation (Elkins and Sides 2007; Devos and Banaji 2005; Sidanius

et al. 1997; Theiss-Morse 2009). Staerkle and colleagues (2010) analyze the cross-national ISSP national identity data from 33 countries to understand factors that enhance or minimize differences in levels of national attachment among members of minority and majority ethnic groups. They find modestly weaker identification with the nation among members of minority groups, with substantially lower levels of attachment in roughly half the countries included in their data. This suggests a slight average difference in levels of national attachment by ethnic groups but also considerable cross-national variability. They also find consistently stronger ties between ethnic and national identity for members of the majority than minority groups. In the United States, Huddy and Khatib (2007) find that Blacks expressed lower levels of national pride but not national identity in the 2004 GSS-ISSP identity module, although this difference disappeared once items referring to equal treatment of groups and the country's history are removed from the scale.

It is less clear, however, that levels of nationalism differ by majority and minority ethnic group status. In research by Huddy and del Ponte (2021) Black Americans were less patriotic but more nationalistic than Whites after controlling for the other type of national attachment and demographic factors. In New Zealand, minority ethnic status was not associated with level of patriotism but was associated with higher levels of nationalism (Osborne et al. 2017). Higher levels of nationalism among members of minority groups is puzzling, especially in analyses that include controls for other factors with which nationalism is often associated such as education. More work is needed to better understand this relationship. Nonetheless, minorities are not less nationalistic than majority groups.

Apart from differences in levels of national attachment by majority-minority status, there are also important questions concerning the political effects of national attachments. Do they have the same meaning and effect among members of majority and minority groups? Carter and Perez (2016) find that national pride increases anti-immigration attitudes among White Americans but has the opposite effect, promoting support for immigration, among Blacks.

Nationalism has more uniform effects among majority and minority groups. Huddy and del Ponte (2021) report that strongly nationalistic Whites and Blacks oppose immigration and support protectionist economic policies to the same degree. But the effects of nationalism can also differ by majority-minority status. In the United States, nationalistic Whites have been increasingly attracted to the Republican Party over the last two decades and vote for Republican presidential candidates whereas Blacks have not. This occurred despite slightly higher levels of nationalism among Black than White Americans in all three ISSP/GSS national identity modules collected in 1996, 2004, and 2014. Obviously, other factors such as group interest and group alliances come into play in translating national attachments into political attitudes.

5.2. Explaining Different Levels of National Attachments

Researchers have attempted to understand factors that enhance and diminish differences in national attachments among members of minority and majority ethnic groups. There is some evidence that levels of patriotism differ across geographic contexts among members of minority groups. Wolak and Dawkins (2017) find higher levels of patriotism among members of minority groups living in states with greater racial and ethnic diversity. In

the least diverse states, non-Whites were less patriotic than Whites whereas there was no difference between Whites and non-Whites in states with higher levels of diversity. Some point to economic factors such as the provision of welfare benefits that may sharpen ethnic boundaries and weaken national attachments among members of minority groups. In support of this supposition, Staerkle and colleagues (2010) found that national attachments were weaker among members of minority than majority groups in highly developed, ethnically homogeneous, welfare-based state economies such as Sweden.

The distribution of political power may also influence the degree to which members of minority groups feel attached to the nation. Green (2020) noted that ethnic and national identity align when an ethnic group holds political power in sub-Saharan Africa but that national identity may wane among members of ethnic groups when they are out of power and ethnic identity is stronger than national identity. Ray (2018) demonstrates that ethnic groups who lack access to power report lower levels of national pride than ethnic groups who experience economic inequality. Drawing on data from World Values Survey from 59 countries conducted between 2010 and 2012, Ray finds lower levels of national pride among members of ethnic groups who lack political power or had been subjected to political discrimination.

6. FUTURE DIRECTIONS

One of the challenges confronting researchers interested in the political effects of national attachments is to achieve greater consensus on their definition and measurement. It is difficult to understand when national attachments will bring about greater national cohesion or generate internal divisions when studies differ in how they measure a given concept or use the same measure to tap different concepts. The rich data contained in the ISSP national identity modules provides an excellent starting point for the analysis of national attachments, their structure, measurement, conception as scales or typologies, and the assessment of measurement invariance across nations. The data also has its limits. Panel data would provide a very welcome addition to research on national attachments, allowing political psychologists to better understand the underlying stability of different types of national attachments, and compare the relative stability of measures over time. This would help to answer important questions such as whether someone's level of nationalism changes in response to ongoing events such as an influx of immigrants or economic challenges, or whether political parties capitalize on such changes to increase the political salience of nationalism.

The conditions under which national unity can be enhanced or undermined among those who identify strongly with the nation and express strong patriotic feelings is also worthy of greater research attention. It is clear from recent events in the United States that partisan divisiveness can readily fracture national unity. But what are the limits to this process? Social identity theory sheds some light on this process, by emphasizing the conditions under which national identity is salient, such as in the presence of an external enemy. The theory helps to explain why national identity and pride generate national trust and solidarity. But social identity theory sheds less light on the existence of nationalism and its divisive effects on support for immigration, diversity, and political tolerance.

As noted, the recent rise in support for nationalist parties and political leaders cannot be traced to rising levels of nationalism. Aggregate levels of nationalism have remained relatively constant in the United States and western European countries in recent years. Instead of increasing levels of nationalism, nationalist parties increase the political relevance of nationalism. If nationalist parties make nationalism more salient but do not increase levels of nationalism, we need to better understand the conditions that foster their emergence. Is it increased cultural and ethnic diversity within a nation that allow such parties to gain traction? An economic crisis? Threats to a nation's dominance? Testing the conditions under which nationalistic rhetoric is deemed more and less acceptable, or a nationalistic candidate gains more and less support, may provide a good starting point for this line of research.

Lower levels of patriotism but comparable levels of nationalism among members of majority and minority ethnic groups deserves future attention. What are the political consequences, if any, of such differences? Black Americans may score lower than Whites on standard measures of patriotism, but they vote at higher rates once racial differences in educational attainment are controlled (Bowler and Segura 2012). In the United States, nationalism has increasingly driven White but not Black support for the Republican Party, creating clear racial limits to the success of nationalistic rhetoric in ethnically diverse nations. More research is needed to understand the meaning of patriotism, nationalism, and their political effects for members of diverse racial and ethnic minority groups across nations. It is heartening to see an emerging line of recent research on the factors that promote a sense of national belonging among diverse citizens. This is an important area of future research.

I hope this chapter has made clear the value of a psychological approach to the study of national attachments. Past research on pride and national chauvinism has spawned a variety of scales and concepts, drawn differing normative conclusions, and has been characterized by conflicting and contradictory terminology and measurement. It is not uncommon to find the same survey question being labeled quite differently by different researchers. Better measurement, clearer concepts, and a stronger theoretical focus will help to advance research within this area. National attachments are essential to the smooth functioning of the modern nation-state. Patriotism fosters tax compliance, civic engagement, pride in national culture, history, and achievements, and a willingness to help nationals. National cohesion can be fractured, however, by resurgent nationalism, which restricts national belonging, generates hostility toward foreigners, and places limits on international cooperation. As the world confronts problems that are beyond the control of any single nation, an understanding of the dynamics that propel a nation toward cohesion and international cooperation or toward chauvinism and nation-first policies could not be more pressing.

NOTE

1. Schlipphak (2013) and Teney et al. (2014) find that support for the EU, immigration, and free trade are related and pertain to attitudes toward supranationalism and international cooperation more generally.

CHAPTER 22

THE SOCIAL IDENTITY APPROACH TO POLITICAL LEADERSHIP

FRANK MOLS, S. ALEXANDER HASLAM,
MICHAEL J. PLATOW, STEPHEN D. REICHER, AND
NIKLAS K. STEFFENS

1. THEORIZING LEADERSHIP

WHY do some individuals emerge as effective political leaders while others do not? Why are some politicians able to mobilize people to produce transformative societal change? Why do ordinary citizens at times become enthralled with authoritarian leaders? These are some of the questions that have preoccupied social scientists—particularly political scientists, sociologists, psychologists, and management theorists—for many decades (for more on leadership research in political science and international relations see Levy, Chapter 10, Stein, Chapter 11, and Casler and Yarhi-Milo, Chapter 12, this volume). However, scholarly interest in leadership began much earlier and can be traced back to the writings of philosophers who sought to provide answers to *normative* questions about good (ethical and effective) leadership. For example, in the *Analects*, written in the period 475–221 BCE, Confucius reflected on the question of “what makes a good ruler?” and answered that “moral cultivation” is the key to what we would nowadays refer to as “good, ethical governance” (Adair, 2013). Likewise, in *The Republic*, written around 375 BCE, Aristotle outlined his views about “good” (virtuous) leadership. Leadership roles, he argued, should be reserved for educated *philosopher kings*, who are “in love with wisdom and truth seeking,” who have attained certain virtues, such as prudence, fairness, courage, restraint, and who have the ability to set aside personal self-interest (Bauman, 2018; Takala, 1998).

In the 16th century a radically different view about what constitutes good and virtuous leadership was advanced by the Florentine diplomat Niccolò Machiavelli. In his 1532 book *The Prince*—a “how-to” guide for rulers eager to retain power—Machiavelli argued that leaders and citizens have a shared interest in protecting state authority, and that all means (ethical or unethical) can be justified to secure this end, including murder, betrayal, and

stoking division (Skinner, 1978). Likewise, Thomas Hobbes advanced a pragmatic approach to leadership in his 1651 treatise *Leviathan*. Hobbes too believed that in a dangerous world marked by constant violent conflict (which he described as humanity's "natural state"), leaders should be realistic and decisive. However, rather than focusing on leader *self*-preservation, Hobbes was preoccupied with ways to secure peace and stability, and the solution he proposed was a social contract in which citizens submitted themselves to government in exchange for protection. Without a social contract of this kind, Hobbes argued, life would be "solitary, poor, nasty, brutish and short" (Hobbes 1651; cited in Riley, 2009: 25).

During the Enlightenment, interest in identifying normative or prescriptive ideals about "good governance" resurfaced, spurred on by dissatisfaction with absolutist monarchs claiming to have been granted the "divine right" to rule. It was during this era that leadership came to be viewed as anchored in popular consent. For example, in his 1689 book *Second Treatise of Civil Government*, John Locke contemplated ways to prevent the abuse of power and argued that this could only be achieved by governing with the consent of the general population (Hoff, 2015). Locke saw effective leadership as involving a partnership between rulers and the ruled in which each citizen "seeks out, and is willing to join in society with others, who are already united, or have a mind to unite, for the mutual preservation of their lives, liberties and estates" (Locke, 1689: 70–71). Along related lines, in *De l'Esprit des Lois*, written in 1748, Charles Montesquieu compared the virtues of different systems of government and made the case for the strict "separation of powers" as a means of preventing power abuse and protecting citizens' rights (Kingston, 2008). Power abuse, he contended, would erode the public's trust in leaders, and in turn render society unstable.

As can be seen from this short list of examples, early thinking about leadership was primarily concerned with the psychology and behavior of leaders but, over time, increasingly recognised that it hinged on a leader's ability to form a successful partnership with followers. This realization paved the way for the study of *followership* to become a central concern in contemporary leadership research (Uhl-Bien et al., 2014). A question of particular interest among contemporary researchers is why certain leaders have a remarkable capacity to inspire and mobilize followers while others seem to falter or fail at this endeavour. Indeed, followership has become a hot topic in contemporary election studies, with political scientists focusing on the relationship between partisan identification (partisanship) and political behavior.

In what follows, we seek to explain how psychological theorizing can be used to enrich our understanding of leadership by exploring its links to followership and partisanship. However, it is useful to first clarify how we define leadership. In line with standard definitions, we define this as "the process through which one or more people influence other group members in a way that motivates them to contribute to the achievement of group goals" (Haslam et al., 2015: 648). It is also worth clarifying that we view leadership not as the capacity to exert power *over* people (as per Machiavelli and Hobbes), but as capacity to exert power *through* people (as per Locke, Montesquieu, and Weber; see Turner, 2005). Moreover, while political theorists such as Locke, Montesquieu, and Weber viewed followership through the prism of power through rather than power over, the group *processes* that bind followers to leaders were largely unexplored in their, and other more recent, analyses. Instead, there has been a tendency in leadership research to conceive of followership as the outcome of particular leadership styles (e.g., charismatic leadership,

authentic leadership, transformative leadership), rather than as a resource that would-be leaders build up over time through a process of mutual social influence.

Our aim in this chapter is to provide a forensic examination of the way in which this resource is created and mobilized. We do this by arguing that effective leadership works primarily through a process in which leaders contribute to building a sense of shared identity with other group members (a sense of “us-ness”), and subsequently tap into that shared identity to garner followership and capacity to secure social change (Haslam et al., 2011). In this way, it is the *coordinated* endeavor of leaders and followers, framed by a sense of shared psychological group membership that allows them to work together to advance the interests of the group.

In advancing this argument, the chapter is organized into three sections. First, we review different phases in contemporary leadership research in social and organizational psychology, paying particular attention to the tendency to overlook group dynamics and instead rely on explanations couched in terms of individual differences. In this section we discuss and unpack core concepts, offer a critique of popular theories and methodological approaches, discuss key empirical findings, and identify the primary problems that prevailing models encounter and fail to resolve. After this, we introduce the social identity approach to (political) leadership. This argues that for leaders to be accepted and gain power through others, they have (a) to be perceived as representative of a group membership that they share with followers (“being one of us”), (b) to be seen as championing group goals (“doing it for us”), (c) to actively cultivate and harness shared social identity (“crafting a sense of us”), and (d) to initiate structures that enable group members to enact their shared social identity (“making us matter”). We then conclude this chapter with a section that argues for the need to step up efforts to draw on social identity theorizing to interrogate group processes in ways that will enable us to better understand the group processes driving *partisanship* (Campbell et al., 1980; Huddy, Mason & Aarøe, 2015; West & Iyengar, 2020), *elite influence* (Feldman et al., 2012; Zaller, 1992), and *affective polarization* (Huddy & Yair, 2021; Druckman & Levendusky, 2019).

2. CONTEMPORARY LEADERSHIP RESEARCH

Contemporary leadership research developed in three partly overlapping phases (Haslam & Reicher, 2016). The first phase was associated with research into *charismatic leadership*, and focused (in a gendered way) on “great men” and the source of their charisma. This was followed by a wave of research that sought to do greater justice to contextual variables and motivational factors, with researchers seeing leadership as involving person—situation fit, rational choice, and social construction. Finally, in recent decades, researchers have once again returned to seeing leaders’ capacity to secure compliance and followership as flowing from particular leadership styles (e.g., in the form of inspirational, transformative, or authentic leadership).

2.1. Phase 1: “Great Men” and Their Charisma

As Lindholm observed in his 1990 book *Charisma*, the idea of the exceptional heroic leader has been around for a long time. It features in Plato’s *Republic* (375 BCE), Aristotle’s

Nicomachean Ethics (340 BCE), Comte's *Calendar of Great Men* (1849), Mill's (1859) description of leaders as individual geniuses, Carlyle's *Great Man Theory of History* (1840), Nietzsche's depiction of an *Übermensch* ("superman") as an ideal-type leader (1885), Le Bon's writings on the hypnotic crowd leader (1900), and Weber's work on "charismatic leadership" (1922) (for overviews, see Lindholm, 1990; Potts, 2009). What these authors shared was a belief, articulated by Francis Galton in his 1869 book *Hereditary Genius*, that human progress is the creation of "great men" who are "born special" and "made of the right stuff." As the pre-Socratic philosopher Heraclitus put it: "the many are worthless, good men are few; one man is worth ten thousand if he is the best" (Kahn, 1981: 57), a view echoed by Thomas Carlyle when he declared that "universal history, the history of what man has accomplished in this world, is at bottom the history of the great men who have worked here" (Carlyle, 1840: 3).

Such observations speak to a long history of leadership scholars glorifying "great men" (to the exclusion of "great women") and perpetuating the idea of charisma as a special gift that only some people possess, in line with the original meaning of the ancient Greek word *khárisma* as a "special gift." This "heroic" view continues to inform lay understandings of the topic. For example, it is seen in the popular biographies of politicians, CEOs and sports coaches which glorify leaders by portraying them as capable of achieving remarkable things as a consequence of their unique personalities. In other words, the key premise of this approach is that people are great leaders by dint of what sets them apart from the masses. According to such accounts, leaders who achieved great things did so more or less singlehandedly by virtue of their remarkable personality and charisma (e.g., "Churchill defeated Nazi Germany," "Gandhi secured India's independence," "Lincoln ended slavery").

There are fundamental problems with this heroic view. For example, while some leaders are clearly more effective than others, it is also clear that rather than being "born to lead," leaders' propensity for leadership is shaped by their life experiences. In the mid-20th century this point was explored extensively by Frankfurt School sociologists in their efforts to explain the remarkable appeal of authoritarian leaders and regimes (see Feldman & Weber, Chapter 20, this volume). In particular, they grappled with the fact that the Great Depression of the 1930s had failed to trigger a global working-class uprising as traditional Marxist social theory predicted, and struggled to explain why the deprived working classes put their faith instead in authoritarian leaders who reinforced rather than challenged the unequal status quo (Eyerma, 1981). Inspired by Freudian psychology, these scholars began to study the life stories of totalitarian leaders, paying particular attention to such things as early childhood trauma, repressed aggression, and sexuality (Jay, 2019). In the process, they became early adopters of a *biographical approach*, which involved retrospective inquiry to discover early signs of greatness, depravity, and adversity in the personal histories and life stories of (in)famous leaders (see also Bennis & Thomas, 2002).

Frankfurt School scholars also invoked early childhood experiences to explain how an entire generation of ordinary Germans could become enthralled by Hitler's authoritarian leadership. Hitler was able to gain a mass following, they reasoned, because ordinary Germans growing up during the Great Depression had been subjected to harsh child-rearing styles which manifested in later life in a collective "authoritarian syndrome" (Adorno et al., 1950). Although early Frankfurt School scholars viewed personality not as fixed but as structured by social relations and social experiences, and hence potentially changeable¹ (Fromm et al., 1989), this nuance was missing from later analyses in which researchers proposed there are measurable individual differences in the extent to which individuals would be drawn to authoritarian leaders—differences that could be captured by relevant measures (notably,

the F-Scale and the Right-Wing Authoritarianism Scale, Adorno et al., 1950; Altemeyer, 1988). Alongside this, Frankfurt School researchers also extended leadership research by introducing considerations of *followership* into their analysis of leadership. And while they embraced an individualistic conception of followers (as individuals with particular personality traits unwittingly gravitating towards particular kinds of leaders) they nevertheless recognized that followership is an indispensable part of the leadership jigsaw.

Importantly too, Frankfurt School scholars were also interested in group processes and collective meaning making. However, this process was viewed in a top-down manner, as a process through which powerful elites control the means of cultural production (e.g., through art, movies, television) to further their vested interests, and are thus able to manipulate the masses into a state of “false consciousness.” What remained underexamined was the (bottom-up) transformative influence that followers exert over leaders, and the dynamic processes through which leaders and followers cue each other (Feldman et al, 2012). Moreover, scholars in this tradition failed to take on board Weber’s insight that charisma is *conferred* on leaders by followers (Weber, 1946), and that leaders earn but can also lose their reputation as charismatic leader (Milosevic & Bass, 2014). Indeed, recognizing this point makes the broader debate about whether or not leaders are “born to lead” redundant, since it is clear that leadership can never be achieved without the participation of followers.

However, Weber himself was ambivalent on this point. At times he emphasized the subjectivity of perceived charisma, but elsewhere he portrayed charisma as a leader characteristic—for example, when arguing that charismatic leadership would be required to save the masses from themselves. Thus in his 1922 essay *The Sociology of Charismatic Leadership*, he outlined the extraordinary characteristics that he believed charismatic leaders would need to possess in order to be able to inspire others with their vision and mission (Weber, 1946). In this way, his work paved the way for interest in those traits that mark out charismatic leaders, as well as in the quest to identify effective leadership styles (e.g., House & Howell, 1992). Ultimately, though, these efforts were unsuccessful. In particular, influential reviews that were conducted around the middle of the century concluded that none of the traits that the literature identified as important for leadership (e.g., intelligence, extraversion, dominance) reliably predicted its success (e.g., Mann, 1959). Instead, the usefulness of these variables was observed to always depend on a further factor, namely the *social situation* (Stogdill, 1948). Moreover, while findings of more recent meta-analyses suggest that individual traits (such as the Big Five personality traits) are associated with indicators of leader *role* performance (Bakker, Chapter 2, this volume; for reviews, see Do & Minbashian, 2020; Lord et al., 1986 Derue et al., 2011), these findings do not help us understand the process through which aspiring leaders are able to build a following (Haslam et al., 2020).

In summary, then, early 20th-century leadership research described ideal-type leaders in ways that relied heavily on individualistic “heroic” leadership models, with researchers either assuming that charismatic leaders are innately special and therefore destined to succeed, or that they can acquire traits and skills that enable them to succeed at all times and under all circumstances. This heroic view continues to inform lay understanding of leaders’ abilities to achieve remarkable things. Moreover, although more leadership research now pays more attention to contextual factors and group dynamics (e.g., Hollander, 2012), on the whole psychological research into leadership and followership has continued to rely heavily on personality and trait-based explanations (e.g., Barber, 1992; Deinert et al.,

2015; DeRue et al., 2011; Hargrove, 1966; Lilienfeld et al., 2012; Tucker, 1977; Renshon, 1994). Nevertheless, over time, there has been increasing recognition that (political) leadership success is subjective (Weber, 1946), context-dependent (Stogdill, 1948) and bound up with shared values and beliefs (George, 1968), and hence not reducible to personality alone (Winter, 2005). No leader is an island, and to understand their leadership properly we need to understand their relationship with the followers who make it possible.

2.2. Phase 2: The Contingent Nature of Leadership and Followership

As Mintzberg notes (2004), the “great man” approach to leadership continues to wield considerable influence in society at large and is reflected in popular conceptions of the topic. However, in the field of leadership studies, confidence in the approach has gradually waned—in both psychological and political science. As we intimated above, two bodies of evidence have led researchers to abandon the heroic view of leadership. One centres on growing evidence that leadership success is the contingent product of personal and situational factors; the other on the observation that leadership success is necessarily dependent on a leader’s acquired capacity to garner followership.

Together, these two insights led to a second phase of research in which researchers sought to account for the context-dependent nature of leadership success. For example, historians and sociologists advanced what became known as the *situational approach*, arguing that particular contexts (e.g., an economic crisis) will provide fertile soil for certain kinds of leaders (Cooper & McGaugh, 1963). According to this perspective, particular conditions “produce” particular kinds of leaders (as per the aphorism “cometh the hour, cometh the man”), with the implication that any leader who happens to rise to prominence might easily have been someone else *like* them. For example, proponents of this approach would argue that if it had not been Hitler who seized the moment and capitalized in on ordinary Germans’ frustration with the Weimar Republic, it would have been someone else with a similar leadership style.

As an extension of this point, organizational psychologists advanced a *contingency approach* (e.g., Fiedler, 1964; Fiedler & Garcia, 1987), which viewed leadership success as dependent on the quality of the match between individual leaders and the situations they confront (Gibb, 1958). There are a range of ways in which this approach has been realized theoretically and practically. At heart, though, it argues that leadership can be understood (and assessed) with reference to three core elements: first, the character of leaders (e.g., their relationship- or task-focus); second, relevant features of the leadership context (e.g., the need to build relationships or complete tasks); and third, the optimal fit between these two elements.

Situational and contingency approaches have both helped to increase awareness of the context-dependent nature of leadership success. However, both are informed by an assumption that leaders have an immutable personality that helps them to succeed, and that manifests itself in the same way over time and across a broad range of contexts (Haslam et al., 2020). Yet in recent years this assumption has been increasingly called into question, not least because evidence suggests that leadership effectiveness rests on a

leader's capacity to *adapt* to the context in which they find themselves. Indeed, what contingency approaches fail to account for is the *dynamic interactionism* whereby leaders (e.g., politicians) and followers (e.g., voters) cue and change *each other* (Feldman et al., 2012; Hooghe & Marks, 2005; Steenbergen et al., 2007). Among other things, this means that leaders need to tailor their style according to the context in which they and their group find themselves (Reynolds et al., 2010). Related to this observation, a further failing of contingency approaches is that only the leader is ever subjected to serious psychological analysis. However, as we have noted, a large part of the context that confronts any leader is constituted by followers who are necessarily bound up with the success of leadership (Bennis, 1999; Platow et al., 2015). As with heroic approaches, a core problem with contingency formulations is thus that they position rank-and-file group members as passive onlookers to the leadership process rather than active participants in it (Reicher et al., 2005; Shamir, 2007).

Mindful of this point, researchers advanced new approaches that attempted to take stock of followers' perceptions and motivations. However, these approaches continued to conceive of the leader-follower relationship in a mechanistic way, as one entailing a match between leaders' style and followers' expectations. For example, this is a feature of *transactional approaches* that zero in on the nature of the leader-follower *relationship*. In particular, early work by Hollander (1965, 1985) viewed this relationship as a mercantile exchange that is shaped by rational cost-benefit evaluations in which leaders and followers are motivated to scratch each others' backs, providing the terms of the exchange are fair. In particular, the leaders' contributions to the group are argued to give them (idiosyncrasy) credit to then be able to innovate and deviate from the group's path. Such insights paved the way for the emergence of *leader-member exchange (LMX) theory*, which called for more attention to be paid to the quality of the interpersonal relations between leaders and followers, and argued that high-quality exchange relationships are intragroup partnerships (Graen & Uhl-Bien, 1995; Scandura & Graen, 1984) characterized by a "high degree of mutual trust, respect, and obligation" (Graen & Uhl-Bien, 1995, p. 227). This idea that leadership centres on successful interpersonal transactions accords with principles of *equity theory* (Adams, 1965), which conceive of humans as rational utility maximizers (*homo economicus*), and which see followership as contingent on leaders' ability to ensure followers are satisfied with their ratio of outcomes relative to input and relative to the contributions and rewards of others. A central idea here is that a leader's job revolves around combatting (actual and perceived) freeriding.

Conceptualizing leadership in these terms has intuitive appeal, not least because it is consistent with theories of economic exchange that have widespread currency in the social sciences (Fine & Milonakis, 2009). Nevertheless, a key limitation of these approaches is that the concepts of "cost" and "benefit" are elastic, such that almost anything can be interpreted retrospectively as aligned with "rational" self-interest (Bruins et al., 1995). What is more, it is often unclear whether *self-interest* refers to the individual's interests, or to shared "sociotropic" self-interests. In line with this point, evidence suggests that perceptions of transactional "utility" are highly fluid, and shaped by prevailing values and norms (Selznick, 1957; Uhl-Bien & Carsten, 2018). Indeed, in these terms, much of what leaders actually do involves (re)defining followers' values in ways that fundamentally *recalibrate* transactional algebra—as when John F. Kennedy's invited Americans to "ask not what your country can do for you . . ." (MacArthur, 1996: 486) or when Donald Trump told his followers that they

would pay the price of legal action against him, observing “they’re going after me without any protection of my rights [but] in reality they’re not after me, they’re after you” (January 29, 2022). In other words, leaders do not just give followers what they value; they also tell them *what* to value.

Speaking to the importance of followers’ expectations, research informed by a *perceptual approach* has argued that followers have preconceived ideas about what good leadership looks like and that leaders need to live up to these in order to succeed. In particular, proponents of *leader categorization theory* (LCT) have argued that effective leaders need to behave in ways that conform to established leadership stereotypes (Lord et al., 1982; Lord & Maher, 1990, 1991). Consistent with this analysis, research shows that male political candidates continue to benefit from a baseline association between leadership and being male (Sanbonmatsu, 2002), even though the effect has weakened over time (Eagly, 2007). Similarly, racial ideology was a predictor of people voting for a white candidate in the 2008 US presidential elections (Greenwald et al., 2009). This suggests that non-caucasian candidates continue to face a comparative disadvantage, since a significant segment of the electorate will vote on the basis of race rather than proposed policy.

Again, though, it is apparent that rather than being fixed and immutable, leader stereotypes are labile and responsive to context—and that leadership involves shaping rather than simply pandering to followers’ expectations. This, for example, explains why Barack Obama was able to defeat John McCain, despite 77% of US voters being White (Pew Research Centre, April 30, 2009), and despite Obama’s candidacy triggering a surge in racist sentiments (Tesler, 2013). To explain why many white voters became enthusiastic supporters of an African-American presidential candidate, we thus need to go beyond an approach which sees the terms and expectations of leadership as set in stone, and leaders as powerless to change them. In particular, as we outline further below, to explain the groundswell in support for Obama we need to understand the transformative power of his “Yes we can” campaign, and of the group processes that this mobilized and tapped into.

Importantly too, we need to come to terms with the point that while it centres on issues of power, leadership is more about gaining power *through* followers than it is about having power *over* them. Nevertheless, the *power approach* to leadership has generally focused on the material and psychological resources that leaders have at their disposal (Kerr & Jermier, 1978; French et al., 1959), and studied the conditions under which different kinds of resources are more or less effective in securing others’ compliance (e.g., Kahn et al., 1964; Bacharach & Lawler, 1980). This is problematic because evidence suggests that when leadership is seen as a matter of resources (e.g., as a question of having the means to coerce others), this is generally inimical to influence and often a source of resistance and reactance (Brehm, 1966; Turner, 1991, 2005). To be sure, control over resources can matter, especially if the resources in question are scarce and of valued to others (Reynolds & Platow, 2003). But nonetheless, a concern to wield power *over* people will at best engender superficial, extrinsically motivated compliance (i.e., where followers follow because they feel they *have* to). If one is interested in securing deeper intrinsically motivated compliance (i.e., where followers follow because they *want* to), one therefore needs to focus on achieving this through the “soft” process of social influence rather than the wielding of “hard” material force (Nye, 1990; Gallarotti, 2011; Haslam et al., 2014).

2.3. Phase 3: Transformational Leadership

As Gerstner and Day (1997) note, traditional leadership theories attributed leadership effectiveness to fixed personal characteristics of the leader, to features of the situation, or to an interaction between the two. The downside of treating the leader–follower relationship in this mechanistic way is that it remains unclear what might motivate (potential) followers to follow a particular leader, and why (political) leaders often have very different relations with different (groups of) followers. The third phase in leadership research emerged around efforts to reveal the psychological processes bound up with these dynamics of followership. For example, *path-goal theory* acknowledged that team members have different motivations and viewed leadership challenges as revolving around the need to align the goals of leaders and followers (Evans, 1970, 1996; House, 1971). Likewise, proponents of *vertical dyad linkage theory* argued that in all groups there is typically a highly motivated central ingroup, consisting of team members with close ties to the leader, and peripheral outgroups comprised of team members who are not so committed to the leader’s vision and hence only “go along” with their instructions under duress and with little enthusiasm (Dansereau et al., 1975; see also Reynolds & Platow, 2003).

At first glance, the arguments put forward by these two approaches seem sound. However, both are based on a rather static understanding of groups which fails to appreciate how group goals, boundaries, and commitment can change as a function of social context. Both approaches also fail to acknowledge the capacity for particular forms of leadership to transform relatively disengaged bystanders into actively engaged and intrinsically motivated followers. This is a serious oversight as, after all, a key challenge facing leaders is precisely to persuade potential followers to “come on board” by converting them into enthusiastic ingroup members.

This idea that leadership centers on the process of transforming passive spectators into active followers was central to the writing of political scientist James M. Burns. In particular, he contrasted *transformational leaders* with *transactional leaders* and argued that only the former are able to elevate and capitalize upon the motivations and morals of prospective followers (Burns, 1978). Moreover, Burns argued that by conceiving of leaders and followers as “set apart” in an uneven transactional power relationship, traditional approaches fail to recognize the capacity for leaders and followers to influence and empower each other. At the same time, though, there is some conceptual ambivalence in Burns’ writing because this drew heavily on individualistic psychological theorizing (e.g., Maslow’s hierarchy of needs) while at the same time calling for greater attention to *collective*-level dynamics. Nevertheless, his work laid the foundations for what has probably been the most influential strand of leadership thought and practice in recent decades—*transformational leadership theory* (Bass & Riggio, 2006).

As it has evolved, transformational leadership research has had two key foci—namely the *perceptual approach* and *behavioral approach*. Researchers who have adopted a perceptual approach have generally looked to develop scales to measure and assess the transformative impact of different leadership styles on followers. In this vein, advocates of *multifactor leadership* have sought to capture the nuances of transformational leadership via tools such as the multilevel leadership questionnaire (MLQ; Bass & Avolio, 1997). These recognize the importance of group dynamics and, to this end, typically seek to

capture multiple stakeholders' perceptions of leaders (e.g., through *360-degree feedback*). However, when push comes to shove, the collective dimensions of leadership tend to recede into the empirical shadows—with data from such exercises routinely being used simply to make an assessment of the extent to which a given individual is (or is not) a transformational leader.

Aware of these issues, researchers pursuing a behavioral approach have tried to uncover and understand the dynamics of transformational leadership, typically grounding their understanding of these in the charismatic character of the individual leader. The roots of this approach hark back to Weber's writings that we have already discussed and to research conducted in the 1950s by Fleishman and colleagues (Fleishman, 1953; Fleishman & Peters, 1962). The latter identified approximately 2,000 characteristics of successful leaders and ultimately distilled these down to two that appeared to be particularly predictive of leadership success—namely “consideration” and “structure initiation.” Likewise, in their influential 1982 book *In Search of Excellence: Lessons from America's Best-Run Companies*, Waterman and Peters argued that the twin hallmarks of leader success were “bias for action” and ability to achieve “productivity through people.”

These analyses are often descriptively very rich (as they were in Burns' writing). For example, Yammarino (1994) observes that:

The transformational leader arouses heightened awareness and interests in the group or organization, increases confidence, and moves followers gradually from concerns for existence to concerns for achievement and growth . . . in short, transformational leaders develop their followers to the point where followers are able to take on leadership roles and perform beyond established standards and goals. (p. 28)

More recently too the idea that particular leaders are equipped with extraordinary capacity to transform and engender followership has been a focus for research into processes of *authentic leadership*. Authentic leaders, it is argued, have above-average capacity to foster trust, motivation, and followership, largely because they are equipped with above-average levels of self-awareness, capacity to self-reflect, responsiveness to feedback, and ability to resolve conflict in non-manipulative ways (Avolio et al, 2004; Gardner et al, 2011; Luthans & Avolio, 2003).

It is clear from this literature that leaders who are perceived by followers as transformational and authentic (constructs that have significant conceptual overlap; Banks et al., 2016) do indeed have greater capacity to engender followership. Nevertheless, a number of key questions remain unanswered in the “black box” of transformational theory. In particular, what are the actual *processes* that lead to a given leader coming to be perceived by followers as stimulating and inspirational (van Knippenberg & Sitkin, 2013)? What is it that transformational leaders actually transform? And what actually determines whether followers perceive their leadership as transformational?

In addressing such questions, one point that becomes clear is that rather than being transformational or authentic in the abstract (in ways that the perceptual approach would suggest), these characteristics are always subjective and in the eye of the beholder (Nye & Simonetta, 1996). In particular, followers are more likely to perceive a leader as transformational and authentic when the leader in question is perceived to be an ingroup member (Steffens et al., 2016). By way of example, Democrats generally saw the lewd comments made by Donald Trump in the lead up to the 2016 presidential election as evidence of toxic

masculinity, while Trump supporters saw them as harmless locker room banter that was evidence of Trump's authenticity (Reicher & Haslam, 2017b). Similarly, leaders' perceived authenticity fluctuates as a function of their capacity to deliver things that matter for group members (Steffens et al., 2016). For example, British Prime Minister Boris Johnson's popularity surged (to 66% in July 2020) when he successfully portrayed himself as the only leader able to "get Brexit done," but his approval rating plummeted (to 22% in January 2022) after news broke that he had hosted a series of parties during a period of strict COVID-19 lockdown (YouGov, 2022)—behavior that communicated a sense that he was not interested in following the same rules as everyone else. Again, then, we see that leadership success cannot be explained with reference to leader characteristics alone but that it needs to be understood as grounded in the relationship between the leader and their group (Funk; 1996; Kinder et al., 1980; Laustsen & Bor, 2017).

In summary, then, it is apparent that while treatments of transformational and authentic leadership have homed in on some of the important realities of the leadership experience, they nevertheless neglect the interactive dynamics that bind leaders and followers together as members of a group with a shared mission, purpose and identity. Indeed, by focusing on awe-inspiring leaders and leadership styles but leaving group processes and persuasion out of the equation, leadership research has arguably come full circle. As Conger put it, "the heroic leader has returned [. . .] and the literature is reminiscent of the 'great men' theories, but with a twist given the transformational leaders' strong orientation towards the development of others" (1999: 149). A similar problem plagues election studies, where voters are commonly construed as passive consumers of different leadership styles, and viewed as responding differentially to particular kinds of cues only as a function individual-level differences (e.g., in personality, anxiety, need). However, here too there is growing awareness that politicians read and shape public sentiments (Mols & Jetten, 2020), and that politicians and voters *influence each other* as a function of group memberships that they share to a greater or lesser extent (Hooghe & Marks, 2005; Feldman et al., 2012). To fully appreciate these dynamics, we therefore need a framework which takes the collective group-level dimensions of leadership seriously. This is ultimately what the social identity approach provides, and it is to this that we now turn.

3. WHY WE NEED A NEW APPROACH

It should be clear from the foregoing discussion that leadership research has come a long way over the course of the last century. In particular, we now know that it is important not only to consider context-dependence and situational fit when explaining leadership success, but also to understand followers' motivations when trying to explain leaders' capacity to inspire and mobilize. Related to this point, another literature that has generated important insights into leadership and followership is the burgeoning literature on *partisanship* (Abramson, 1979; Campbell et al., 1980; Huddy & Bankert, 2017; Iyengar & Westwood, 2015; Mason, Chapter 24, this volume). Thanks to this, we now know that followers of political leaders and parties are motivated by a mixture of positive ingroup feelings (positive partisan identity, PPID) and negative outgroup feelings (negative partisan identity, NPID;

Rathje et al., 2021), and that these sentiments often reinforce each other in ways that lead to affective polarization (Huddy & Yair, 2021).

This literature makes it clear that followership is a process of subjective meaning-making that is heavily structured by group dynamics. This is seen, for example, in reactions to politicians who are often simultaneously loved and loathed by different groups of people (e.g., former US President Donald Trump, the late Palestinian leader Yasser Arafat, and British Brexit campaigner Nigel Farage; Steffens et al., 2018). However, polarization of this kind will only occur once relevant social identities have been made salient, and once voters begin to self-identify as supporters of a particular party or leader (Oakes et al., 1994). Once this happens, voters are at risk of ending up in separate echo-chambers where different groups appraise leaders' actions in radically different ways (Finkel et al., 2020; Van Bavel & Pereira, 2018). What is more, politicians often actively encourage "othering" of outgroups, as they stand to gain electorally from whipping up resentment toward the opposing party (through negative partisanship). Importantly too, as can be seen from debate about anthropogenic climate change, leaders will invoke evidence, and present this evidence as irrefutable, even though relevant stakeholder groups typically have different views about *which* evidence should count as policy-relevant (Head, 2008).

In short, both what is perceived as "good leadership" and as valid "evidence" supporting government action are subjective and in the eye of the beholder. This point is made by Deborah Stone in her 1988 book *Policy Paradox*, which urged evidence-based policy researchers to avoid having naïve faith in "objective evidence" and the enlightened "rationality project" (Stone, 1988). In particular, she argued that the emerging evidence-based policy literature has misplaced confidence because it fails to appreciate the fact that evidence itself is often the product of partisan group interests (Wang et al., 2021). The same is true of the leadership literature, where the valorising of leaders' authenticity and transformational potential neglects the fact that appreciation of these qualities is grounded in perceivers' group memberships (Steffens et al., 2016, 2021a).

More generally, consideration of group psychology is often conspicuously absent from traditional leadership research. This is especially true in organizational psychology, where leaders and followers are typically viewed as interacting individuals rather than as members of groups. This is less true in political psychology where there has been long-standing interest in the group, not least via research into (positive and negative) partisanship (Abramson, 1979) and affective polarization (Iyengar et al., 2012). Nonetheless, political psychologists still grapple with the same conceptual challenges as their organizational counterparts. Like followers of the Frankfurt School before them, many continue to ignore social context and to present individualistic accounts of partisan followership which see this as the coming together of voters who share personality traits which lead them to be attracted to particular kinds of messages or rhetoric (e.g., Luttig, 2018). And rather than examine how politicians actively shape voters' perceptions about societal issues, studies typically explain (positive and negative) partisanship and affective polarization with reference to individual differences and hard-wired propensities that voters are believed to enact unthinkingly (for a more nuanced view of leader-follower influence on foreign policy, see Kertzer, Chapter 13, this volume).

As Durkheim (1912 [1995]) observed in his work on "collective effervescence," what these individual-difference explanations overlook is the fact that followers' behavior is often

guided by a distinct “group mindset.” As Gestalt psychologists observed, here the group is *more* than the sum of its parts, and hence group attitudes cannot be understood as the mere aggregation of personal motivations or propensities (Asch, 1952; Turner, 1991). The neglect of group-level dynamics is also an important reason why research is often observed to have limited ecological validity (e.g., Agassi, 1960; Mols & ‘t Hart, 2017).

Given the ongoing appeal of individualistic metatheory (e.g., as noted by Lynch & Kalaitazake, 2020; Steiner, 1974), the need to advance an alternative perspective that recognizes the unique psychological dimensions of collective behavior remains a pressing challenge for leadership research and for political psychology more generally. At a general level this is a challenge that has been met by social identity approach in social psychology (SIT, Tajfel, 1979; Tajfel et al., 1979; Turner & Oakes, 1986; Turner, 1991) as well new-institutionalism theorizing in political science (DiMaggio & Powell, 1983; March & Olsen, 1983). Accordingly, in what follows, we seek to show how insights from a social identity approach can be used to develop a non-reductionist, integrative theory of political leadership.

4. THE SOCIAL IDENTITY APPROACH TO POLITICAL LEADERSHIP

As the forgoing reviews makes clear, previous leadership research has generated a wealth of perspectives both about what effective leadership entails and what it “looks like.” What remains poorly understood, though, are the psychological *processes* that enable leaders to exert transformational influence over the groups they lead (Burns, 1978), and the *conditions under which* transformation can occur. In this regard, a distinctive feature of social identity theorizing is its emphasis on the importance of social groups for people’s sense of self, and hence for both social perception and social influence (Turner, 1991). In particular, self-categorization theory (Turner et al., 1987, 1994) argues that the influence process that is central to leadership is grounded in perceivers’ sense that they share social identity (a sense of “us-ness”) with the leader. Rather than viewing groups as distorting individual group members’ perceptions of themselves and the world or as a basis for individuals to lose their identity and morality (Le Bon, 1896; Zimbardo et al, 1971), the social identity approach instead views groups as strengthening individuals’ sense of connectedness, and as helping them to make sense of the social world *collectively* and to develop *shared* group goals (Turner et al., 1987). Moreover, from a social identity perspective, leaders are able to exert influence through followers precisely as a function of their capacity to transform followers’ self-understanding so that this is informed by a sense of shared social identity—so that leaders and followers define themselves not as “me” but as “us,” and then strive to advance that sense of “us-ness” in the world.

Accordingly, transformation is seen in the social identity tradition as arising from the internalization of new norms, attitudes, and values into group members’ shared self-understanding, such that these new norms, attitudes, and values come to be internalized into followers’ self-concept, and seen as “what we are about” and “what we want to do.” In these terms, political leadership (and social influence more generally) is seen as centering

on power *through* people, and as contingent on a leader's capacity to transform followers' shared self-understanding through processes of *identity leadership* (Haslam et al., 2011; Steffens et al., 2014; van Dick et al., 2018). However, the capacity for a leader to transform followers' shared self-understanding in this way depends on the leader in question being seen by followers as someone who is representative of the group as a whole, who is acting in its interests (i.e., as "one of us" rather than "one of them"), and who is effective in bringing group interests to fruition (i.e., "making us matter").

Seeing political leadership in this way alerts us to two important facets of the leadership process. First, we can see that "trust in fellow group members" is both the reason why individuals gravitate to certain groups and the *consequence* of perceiving shared group membership (Reicher et al., 2005; Platow et al., 2012). Second, we see that groups are eager to develop a *shared understanding* of "who we are" and "what we are about," and that leaders play an important role in reaching consensus about how to answer these questions. Critically, it is this social identity-based sense of shared self-understanding that is absent from traditional understandings of groups that see them only as clusters of individuals attracted to each other through an exchange relationship or as clusters of individuals under the hypnotic spell of a charismatic leader (Hogg, 1992; for a discussion of related elite influence models of public opinion, see Jerit & Kam, Chapter 15, this volume).

That said, there are without doubt clusters of individuals that cooperate in a purely transactional way, without developing a shared social identity (Reynolds & Platow, 2003). However, as social identity researchers have shown in experiments which pit alternative explanations against each other, shared social identification proves to be a more powerful predictor of group cohesion and cooperation between group members than attraction or resource exchange (Haslam et al., 1997; Hogg, 1992). Other studies that have examined the role of shared social identity in social and organizational life also confirm that those who perceive themselves as sharing group membership in a given context are more likely to respect (Platow et al., 2013), trust (Platow et al., 2012), believe (Wang et al., 2021), and help (Platow et al., 1999) one another (Haslam, 2004; Haslam, Reicher & Levine, 2012; Reicher & Haslam, 2009). Indeed, as Van Bavel and Pereira (2018) explain, this is why enthusiastic followers of political parties and their leaders are often immune to countervailing evidence presented by non-ingroup sources.

As noted above, the social identity approach to (political) leadership centers on the observation that social influence is grounded in shared social identification and associated sense of "we-ness" (Turner, 1991). This means that people are influenced by others to the extent that they are perceived to be members of a psychological ingroup ("us"). This, indeed, is why politicians go to great lengths to try to convince perceivers that they are representative of the group they are seeking to lead—whether it be their constituency, party, or country.

In line with this point, there is now a large body of research evidence that shows that shared identity is the key that unlocks social influence. For example, experimental studies show that messages are more persuasive when they are perceived as emanating from an ingroup rather than an outgroup member (e.g., Cruwys et al., 2012; Grace et al., 2008; Haslam et al., 1999; Mackie et al., 1990; McGarty et al., 1994; Oldmeadow et al., 2003; Platow et al., 2005, 2007). Likewise, analysis of speeches by Prime Ministerial candidates in Australian Federal elections found that successful candidates used the pronouns "*we*" and "*us*" much more frequently in their speeches than their unsuccessful counterparts (once every 79 words vs. once every 136 words; Steffens & Haslam, 2013). The conclusion that leaders' success arises

from their capacity to speak (and be perceived to speak) on behalf of the group whose members they are seeking to influence and mobilize has also been corroborated in experimental research with the power to address issues of causality (e.g., Steffens et al., 2014). Among other things, these studies provide empirical affirmation of Adair's (2011) observation that the most useful word in a political leader's vocabulary is "we," and the least useful word is "I." At the same time too, other research shows that leaders who *lack* shared social identification with followers are more likely to resort to "sticks and carrots" techniques to secure power *over* them (Reynolds & Platow, 2003; Steffens et al., 2018).

Two important lessons emerge from this growing body of leadership research. First, it is clear that for aspiring leaders to be accepted they have to be perceived by followers not only as a fellow ingroup-member (i.e., "one of us"), but also as a model group member. That is, they need to be seen as *prototypical* of the group so that they are understood to embody what "we" are about (Hogg, 2001; Steffens et al., 2021b; Turner & Haslam, 2001; van Knippenberg, 2011; after Rosch, 1978). In other words, it is not enough to be perceived as typical, but necessary to be viewed as extraordinarily typical (i.e., prototypical). Second, it is clear that rather than prototypicality being a given, influential leaders are creative *identity entrepreneurs* who (re)define followers' shared self-understanding in terms of shared social identity and who are able to portray their political project(s) as epitomizing "what we are all about" (Reicher & Hopkins, 2000).

These are arguments that we unpack in more detail in the sections that follow. We do this by zeroing in on four key ways in which social identity is critical to political leadership. As we will see, these involve not only identity prototypicality and identity entrepreneurship but also *identity advancement* and *identity impresarioship*. A critical point here is that ultimately leadership is about "walking the walk" of identity leadership not just "talking the talk." So as well as representing and creating a sense of "us," this involves advancing group interests and creating identity-embedding structures.

5. IDENTITY PROTOTYPICALITY: BEING "ONE OF US"

As we intimated above, a key ingredient of effective leadership is perceived prototypicality. This means that an aspiring leader will have more potential for influence the more representative they are seen to be of the group they are seeking to lead. This principle is derived from self-categorization theory's argument (a) that social identity provides a basis for social influence by providing a platform for a sense of shared understanding of the world, but (b) that people differ in the degree to which they are seen to exemplify a given social identity (Turner, 1991).

This insight runs counter to earlier research which argued that leaders' influence derives from fixed abstract leader characteristics, such as intelligence (Judge et al., 2004; Lord et al., 1986), fairness (Michener & Lawler, 1975), and charisma (Bono & Judge, 2004), or even height (Judge & Cable, 2004). As noted above, leader characteristics such as these can matter for leader *role* performance. However, we contend that such characteristics are generally perceived through the lens of group membership. In line with this point, there is

evidence that in-group prototypicality affects how followers evaluate would-be leaders on these various dimensions—such that the more a leader is perceived to be “one of us,” the more intelligent, fair, charismatic, and even tall, they are seen to be (for a review, see Haslam et al., 2020). Such findings suggest that rather than being *inputs* into the leadership process, these various qualities are often *outputs*, and the outcome of shared psychological group membership (Platow et al., 2015).

The claim that perceived prototypicality takes precedence over abstract leader characteristics is supported by a growing body of empirical evidence. In particular, evidence shows that leaders’ capacity for influence derives in large measure from their status as ingroup-prototypes (McGarty et al., 1992; Hogg, 2001; Hogg & van Knippenberg, 2003), and that perceived prototypicality predicts followership more reliably than perceived leader characteristics (Steffens et al., 2015), particularly as the group becomes more important to respondents (Hains et al., 1997). Evidence also confirms that perceived prototypicality enhances trust in leaders (Giessner & van Knippenberg, 2008), perceived leader fairness (van Dijke & de Cremer, 2008), and perceived leader charisma (Platow et al., 2006).

A number of additional points are important to bear in mind in relation to perceived prototypicality. First, we noted earlier that a central feature of the leadership process is leaders’ ability to lead their group in new directions. Here, though, leaders need to be careful not to go out on a limb. Before they can drive change (and secure what Hollander, 1958, referred to as “idiosyncrasy credit”), they first have to earn followers’ trust by showing how their proposals align with existing group norms (Abrams et al., 2008). In the context of seeking to innovate, leaders will therefore often (need to) go to great lengths to highlight their ingroup prototypicality. For example, in the context of pursuing a radical right-wing agenda, the Dutch politician Geert Wilders, was careful to hide his Indonesian heritage (e.g., by bleaching his hair; Van Leeuwen, 2009).

Yet by the same logic, politicians can also undermine their ability to secure followership and compliance with their directives if they act in ways that communicate their departure from group norms. For example, in 2021 the British Health Secretary Matt Hancock was forced to resign after he was found to have broken his own COVID-19 rules during a strict lockdown while pursuing an extra-marital affair. Likewise, as we have already observed, Prime Minister Johnson’s popularity plummeted when he was discovered to have attended a number of parties in his Downing Street office in clear violation of COVID-19 health directives (for a review, see Haslam et al., 2021). Such examples speak to the point that leaders’ influence will typically dissipate if they are seen to behave in a way that sets them apart from their group (e.g., so that there appears to be different rules for “them” and for “us”). Social identity theorists have also confirmed this effect empirically, with results of experiments showing that perceived prototypicality affects not only followers’ willingness to support leaders’ proposals for change, but also the extent to which a leader is able to pursue a change agenda without losing support (Platow & van Knippenberg, 2001).

Would-be leaders can also gain or lose prototypicality inadvertently as a result of changing circumstances. For example, before the 2003 US-led war on Iraq, US newspapers described the hawkish US Defense Secretary Donald Rumsfeld as an extinguished volcano, but once war had been declared he emerged as one of the most prominent leaders in President Bush’s administration. This speaks to the fact that intergroup conflict typically serves to bolster the prototypicality of leaders who seek to define themselves in opposition to relevant outgroups (e.g., by supporting war; Rabbie & Bekkers, 1978). Such examples also make the point that

changes in context (e.g., from peace to war) often change the relative salience of a particular categories and particular category exemplars (e.g., so that in the case of a war, party affiliation will become less salient than national affiliation), and this will often change perceivers' appraisal of which leader is best able to represent and protect the group's interests (Turner & Haslam, 2001). Importantly, such changes cannot be explained with recourse to personality, but instead require an analysis that accounts for political leaders' capacity to benefit from enmityship (Engels, 2010).

But in this context it is important too to acknowledge that leaders generally do not just sit around and wait for their prototypicality to become apparent to followers. Rather, they go to considerable lengths to *make* this apparent. For example, former Polish President Lech Wałęsa—who began his working life as shipping yard electrician before becoming Poland's most famous trade union leader—was always careful to ensure voters remembered he was a working-class hero (e.g., stating in 1970 that “I worked here [in the shipyard] for ten years and I still feel I’m a shipyard worker”; Stokes, 1993: 35). In very different ways, former US President Donald Trump was also able to persuade a large number of voters that he was “one of us” through his advocacy for “ordinary Americans” (e.g., when shouting “I am your voice” during mass rallies; Reicher & Haslam, 2017b). Thus he pronounced:

My Dad, Fred Trump, was the smartest and hardest working man I ever knew. [. . .] It's because of him that I learned, from my youngest age, to respect the dignity of work and the dignity of working people. He was a guy most comfortable in the company of bricklayers, carpenters, and electricians and I have a lot of that in me also. (RNC, July 21, 2016)

Critically too, Trump also sought to make a case for his own prototypicality (and thus leadership) by seeking to undermine the perceived prototypicality (for ordinary American working families) of his Democratic opponent, Hillary Clinton. This was something he did by casting her as representative of the country's corrupt elite (Maskor et al., 2020):

Big business, elite media and major donors are lining up behind the campaign of my opponent because they know she will keep our rigged system in place. They are throwing money at her because they have total control over everything she does. She is their puppet, and they pull the strings. That's why Hillary Clinton's message is that things will never change.

More generally, Trump's success in the 2016 election speaks to the fact that leadership is never about the possession of some set pre-defined leadership qualities. Indeed, exit polls suggested that on every measure of character and suitability for the presidency, Clinton had a clear lead over Trump. She was seen as better qualified (53 vs. 37%), as having the right personality and temperament (56 vs. 34%), as being less dishonest (59 vs. 65 percent), and as being less unpopular (54 vs. 61%; Reicher & Haslam, 2017a). The fact that Clinton received a majority of all votes suggests that these evaluations matter. However, ultimately the bid for the White House was won, not by the leader who was perceived to possess the right traits, but by the leader with the most enthusiastic following, who was capable of swaying the vote in their favor in key swing states. In this way, leadership rests not on a leader being “good” in the abstract but on them being seen to be mobilizing their qualities in the service of an ingroup. As one Trump supporter (Republican Duncan L. Hunter) put it: “He may be an asshole, but he's *our* asshole” (cited in Reicher & Haslam, 2017b; see also Steffens et al., 2021a).

6. IDENTITY ADVANCEMENT: DOING IT FOR “US”

Yet while it is important for leaders to be seen as “one of us,” this alone is not sufficient for them to secure the support of followers. In particular, this is because they also have to champion ingroup goals. In other words, they also have to be seen to be “doing it for us.” Early leadership research informed by the perceptual approach argued that humans have implicit views about what good leaders look like (e.g., confident, self-aware, considerate), and hence that a leader who fits this preconceived image will have greater capacity to engender followership (Kenny et al., 1994; Lord et al., 2020). As we noted earlier, one of the leader characteristics that has been a particular focus for research attention is fairness. But what does fairness look like—especially for followers? As we will see, answering this question proves complex, but the key point is that this is a quality that followers always appraise through the lens of a salient group membership.

One point to note is that perceptions of leader fairness vary depending on which criteria these are evaluated against. One important distinction here is between distributive justice (i.e., a belief that resources have been allocated fairly) and procedural justice (i.e., belief that a decision-making process is fair and transparent). Research by Tyler and colleagues supports the general claim that when these two variables are pitted against each other, it is perceived *procedural* justice that most reliably predicts leader endorsement, followership, and norm compliance (Tyler et al., 1985). Moreover, this work moves beyond the general claim that perceived leader fairness is essential for maintaining group cohesion (Cartwright & Zander, 1960), by showing that a leader can “win over” followers by acknowledging and respecting *group*-level preferences and concerns. In particular, it appears that followers are more likely to forego short-term gains for the benefit of the community as a whole if they feel their views are acknowledged and respected (Platow et al., 1998; Platow, Brewer & Eggins, 2008; Platow et al., 2013; Tyler & Degoey, 1995).

Tyler and colleagues’ work also underlines the point that conceptions of fairness are always bound up with moral communities and that members of these communities (who tend to view the world in us–them terms; Sunshine & Tyler, 2003) will often apply different fairness standards, depending on whether the situation involves in- or outgroup members. For example, people are often quick to condemn an outgroup leader who trespasses, but remarkably forgiving when it is “our leader” who is in the wrong (Randsley de Moura & Abrams, 2013). At times, followers will even change their moral stance when it transpires that their leader has behaved in a way that they had condemned previously. This can be seen, for example, when one looks at responses to NPPR/Brookings polls which ask survey participants in the United States whether an elected official who commits an immoral act in their private life can still behave ethically and fulfil their duties in their public and professional life. In 2011 30% of White Evangelical Protestants believed this to be possible, but by 2016—when the scandal-prone Donald Trump was running for office (Graham, 2017)—this number had risen to 72%. Examples like these show that values and moral commandments are not set in stone but negotiated to suit identity-based interests.

Theory-based experimental studies also provide more specific insight into the *conditions under which* followers endorse fair or unfair leaders (e.g., Platow et al., 1997). In an early study of this form, participants in New Zealand were asked to evaluate a fictitious CEO of a

local health authority responsible for allocating a scarce resource (time on a kidney dialysis machine) to two patients. In one condition the two patients were described as two life-long New Zealanders, and in a second condition one patient was said to be a life-long New Zealander and the other a recent immigrant. The results showed that participants valued fairness (even-handedness) when dealing with two ingroup members, but ingroup-favoring *unfairness* when resources had to be split between the ingroup and outgroup member. Here, then, people's appetite for fairness was clearly bounded by concern for the ingroup.

In an extension of this research, Haslam and Platow (2001, Experiment 2) introduced participants to a student leader who, in the past, had either been even-handed in their support for an ingroup and an outgroup or identity-affirming in favoring the ingroup over an outgroup. They were then asked to write down arguments to support of this leader's proposal to install new billboard sites around campus. Participants who were told the proposal had emanated from the identity-affirming leader generated more than twice as many arguments as participants who thought that it was the argument of an even-handed leader. Again, then, while in the abstract people will generally profess to have an appetite for fairness, their willingness to put their shoulders to the wheel in order to enact a leader's vision will be tempered by their confidence in that leader's willingness to be *unfair* in ways that advance the interests of the group.

In sum, then, it is neither fairness or unfairness per se that enhance a leader's appeal and their capacity to bring about societal change. Rather, what matters is whether the leader is perceived as having group interests at heart. In the Netherlands, for example, former Prime Minister Wim Kok benefitted from his track record as an outspoken Union leader who stood up for workers' rights in his successful bid to become leader of the Labour Party (PvdA). This was also the case during his time as prime minister, when his credentials helped him to persuade Dutch workers and Trade Unions that it was in their best interest to accept wage restraint (as outlined in the, 1982, *Akkoord van Wassenaar*). Likewise, in Israel support for Ariel Sharon's pursuit of the 2005 peace process which led to the withdrawal of troops from Gaza was predicated on his history as a former military leader (Rynhold & Waxman, 2008).

Yet while leaders' pursuit of group interests is an essential feature of their appeal, as these examples illustrate, there is nevertheless considerable variation in precisely how they do this. This is because much depends on the nature of the group in question and, in particular, the norms of the group and what it is that defines group interest (e.g., material vs. moral advance). Among other things, this means that leaders *can* advance group interests by being even-handed in their dealings with outgroups—but this is most likely to appeal to their followers when they have come to value even-handedness and to see it a source of positive distinctiveness for the group (see Haslam et al., 2011). Accordingly, if a leader wants to be fair, one of their first challenges is to help create a community that will appreciate this (Platow et al., 2008).

7. IDENTITY ENTREPRENEURSHIP: CRAFTING A SENSE OF “US”

Thus far we have argued that for leaders to gain influence, they need to be perceived as representative of a shared ingroup identity (“being one of us”) and as champions of group goals (“doing it for us”). In this section, we take a closer look at the ways in which leaders

actually harness social identities for their political causes in practice. Here we propose that leaders gain influence through people (Turner, 2005) by redefining followers' collective self-understanding in such a way that the leaders' political projects come to be viewed as concrete manifestations of the group's beliefs and values. Rather than viewing leaders simply as social identity *interpreters*, we argue that influential leaders also need to be *identity entrepreneurs*, whose influence derives from their creative ability to redefine followers' shared self-understanding, to portray themselves as quintessential group members, and to frame their projects as epitomizing what the group is all about (Haslam et al., 2020; Reicher & Hopkins, 2000; Reicher et al., 2005).

A good example of this process is Lincoln's Gettysburg address, in which he presented his emancipation policy as nothing more than an expression of the values on which America was founded. Another good example is Martin Luther-King's "I have a dream" speech, in which he appealed to the spirit of the Gettysburg Address and argued in a similar vein that the Civil Rights movement was nothing but the realization of American values and identity. As these examples illustrate, politicians who succeed in bringing about landmark societal change generally understand that transforming society goes hand in hand with a transformation in citizens' collective self-understanding (i.e., their shared social identity).

Identity entrepreneurship is a craft which leaders can acquire and hone. Leaders who master this skill will find it easier to navigate what can be understood as a core leadership paradox—that followers want their leaders to be exceptional, yet they also want their leaders to be of them, like them, and not to stand above them (i.e., they want them to be prototypical not just typical). The way in which effective identity entrepreneurs satisfy both needs simultaneously (and resolve the apparent paradox) is by being exceptional in their representativeness of the group (Steffens et al., 2013). In other words, it is by becoming viewed as exceptionally prototypical that leaders gain influence *through* followers (see also Sewell et al., 2021). What is more, identity entrepreneurship involves a double labor. On the one hand, considerable effort is taken to craft a new narrative and a new self-definition, but on the other hand, these efforts have to be hidden so that the leader's account of identity becomes viewed as obvious, natural, and effortless, rather than as artificially constructed and cultivated (Reicher & Hopkins, 2000).

As the following extract from a speech by Belgian radical right-wing politician Filip Dewinter illustrates, leaders of nativist anti-immigration movements are often skillful identity entrepreneurs, who create and tap into a sense of threatened social identity by portraying the group they seek to lead (e.g., the nation) as under attack, and requiring a strong leader to restore order (Reicher et al., 2008; Crimston et al, 2021):

We are experiencing a third Islam invasion. The first one occurred in 8th Century Spain and the second came from the East. Each time brave Europeans stopped the invasion, first in Poitiers in 732, then in Vienna in 1683. Islam is a religion that wants to conquer the entire globe, and historically, Europe has always been its enemy. [. . .] Multiculturalism is the Trojan horse Islam uses to conquer Europe. Comrades, the time has come to show character. We have to end this immigration invasion, defend the superiority of our civilization, stop the Islamization of Europe, and give back Europe to the Europeans. (cited in Mols & Jetten, 2014)

Speaking to the generality of such rhetorical constructions, a similar apparent was seen in Donald Trump's address to the crowd on January 6th 2021 in Washington DC, which set the scene for their subsequent assault on the Capitol building (Haslam et al., 2022):

Our fight against the big donors, big media, big tech, and others is just getting started. This is the greatest in history. There's never been a movement like that. . . . We must stop the steal and then we must ensure that such outrageous election fraud never happens again, can never be allowed to happen again. But we're going forward. We'll take care of going forward. (Naylor, 2021)

However, leaders do not have infinite room to reinterpret social identities and social reality. Rather, they have limited degrees of freedom to reinterpret social identities, and skillful identity entrepreneurs need to be sensitive to how far they can stretch reality and reinterpret the group's shared self-understanding. Successful attempts to redefine followers' shared self-understanding will typically result in norm change (a rethinking of "what we *really* are about"), and hence identity entrepreneurship is as much about redefining "who we are" ("being") as it is about articulating "where we are heading" ("becoming"). What also matters is the degree of contestation in any given context, and whether there are other identity entrepreneurs offering competing versions of "who we are" and "what we are about" (Haslam et al., 2020). For example, in the lead-up to the 2016 US presidential elections, Donald Trump and Hillary Clinton both tried to gain the upper hand by destabilizing opponents' claims to represent and advance group interests. Whereas Clinton sought to turn female voters against Trump by drawing attention to his derogatory comments about women, Trump's strategy was to turn voters against Clinton by portraying her as representative of a self-serving elite (Maskor et al., 2021).

In this context, it is also clear that politicians can sometimes underestimate the importance of social identity management—or at least be caught off guard. For example, the former Labour leader Michael Foot struggled to win popular support with UK voters after being falsely accused by right-wing commentators of wearing informal attire (a donkey jacket) at a Remembrance Day ceremony—something they characterized as disrespectful to the war dead and their families (Haslam et al., 2011). At the same time, there are also many leaders who have fully understood, and fully capitalized on, the importance of representing "us." For example, former US President George W. Bush became renowned for his incoherent language and expressions (so-called *Bushisms*), wearing jeans and cowboy hats, and his taste for steaks and Budweiser beer, and, while in various ways these may all have been "unpresidential," they nevertheless helped him to be widely regarded as an "all-American guy" (Weisburg, 2004). And while a range of factors had a negative impact on his approval ratings (notably the prolonged war in Iraq and questions around his evasion of the draft for service in the Vietnam war; Lardner & Romano, 1999), this cultivated image served him well with the electorate. By way of a more recent example, the British Prime Minister Boris Johnson has been suspected of deliberately messing up his hair before interviews, in an effort to come across as an atypical politician, and to conceal his privileged upbringing (Flinders, 2020). Likewise, former Australian Prime Minister Scott Morrison routinely played up his image as an "ordinary bloke from the shire" by attending rugby games and by showcasing his barbeque skills (Gauja et al., 2020).

Examples like these make the point that identity entrepreneurship involves not just rhetoric, but a wide range of performances that a leader can engage in—including their speech, dress, hairstyle, and leisure activity. What is more, identity entrepreneurs are often able to turn apparent disadvantages into advantages. For example, US President Franklin D. Roosevelt was unable to stand up for long periods of time (after suffering from what at the time was believed to be polio), but he used this to his advantage by drawing parallels

between his *personal* ability to overcome adversity and his ability to lead the nation through the Great Depression (DiNunzio, 2014: 82).

Speaking to the fact that these various acts of identity entrepreneurship are rarely accidental, there is plenty of evidence that politicians are explicitly instructed by campaign advisors to play up their prototypicality. For example, in a 1984 memo, Assistant White House Chief of Staff Richard Darman outlined Ronald Reagan's rhetorical strategy, stating:

Paint Ronald Reagan as the personification of all that is right with or heroized by America. Leave Mondale in a position where an attack on Reagan is an attack on America's idealized image of itself. (cited in Erickson, 1985: 100)

Likewise, in a memo outlining Hillary Clinton's strategy to beat her rival Barack Obama in the 2008 Democratic Primaries, Chief Strategist Mark Penn underscored the importance not only of playing-up Clinton's prototypicality but also of undermining Obama's:

His roots to basic American values and culture are at best limited . . . Let's explicitly own "American" in our programs, the speeches and the values. He doesn't. (McVeigh, Dinsman, Choi-Fitzpatrick & Trivedi, 2011: 52)

What such examples show is that seasoned politicians and campaign advisors understand very well that elections are in many ways a contest about creating alignment between the self and the group, and that in order to secure voter support leaders must find a way to persuade them that they are a quintessential member of the group they seek to represent. For example, on his path to the White House, Donald Trump regularly portrayed "winning" as quintessentially American, but as something that his opponents had lost the ability to do, and in this way his personal achievements could be seen as epitomizing the fulfilment of the American Dream:

Folks, we don't win anymore. Right? We don't win anymore. We don't win! We don't win on anything. We don't win on trade. We don't win with the military. (cited in Shabad, 2016)

I have made billions of dollars in business making deals—now I'm going to make our country rich again. . . . Nobody knows the system better than me, which is why I alone can fix it. . . . I am your voice. (cited in Plumer, 2016)

These various examples speak too to the fact that leaders are generally skillful storytellers (Gardner, 1996)—who tell stories about themselves in relation to the group not just with their words, but with their dress, their appearance, their choice of food, and much else besides. In this way, the stories they tell help to signal the social identity they share with their audience and follow a distinct pattern. For a start, leaders appeal strategically to social identities that seem make sense and are fitting in the context at hand—notably in being defined at an appropriate level of abstraction (Turner et al., 1987). For example, politicians looking to secure support for international development aid will often appeal to shared humanity, while those opposing such aid will typically appeal more narrowly to national interests and people's sense of belonging to the nation. At the same time, identity entrepreneurs typically also look to (re)define the *meaning* of relevant social identities (e.g., what it means to be Scottish, British, Québécois, Canadian), and do this in such a way that the new self-understanding can be leveraged in pursuit of their political projects (e.g., by framing their policy proposals

as naturally aligned with the nation's spirit, values, and aspirations; Reicher & Hopkins, 2000). Thus when President Obama signed his health care act into legislation, he made the case for this by observing that:

The [Affordable Health Care] bill I'm signing will set in motion reforms that generations of Americans have fought for and marched for and hungered to see. [. . .] That our generation is able to succeed in passing this reform is a testament to the persistence and the character of the American people, who championed this cause, who mobilized, who organized, who believed that people who love this country can change it. (Harris & Bailey, 2014: 253)

Importantly too, identity entrepreneurship often takes the form of efforts to redraw category boundaries so as either to expand the ingroup circle (by including previously excluded groups), or by reducing it (by excluding previously included groups). Indeed, in the world at large there is often competition between leaders with opposing views about whether to expand or contract the ingroup circle. An extreme example is seen in Hitler's redefinition of German nationhood ("Volk") as anchored in an ethnic bond so as to exclude Jews from the category "fellow Germans" and thereby pave the way for the Holocaust (Reicher et al., 2008). Yet at the same time Bulgarian leaders explicitly rejected the characterization of Jews as "other" (seeing Bulgarian Jews primarily as Bulgarians) in ways that protected them from harm (Reicher et al., 2006). This example underscores the broader point that identity entrepreneurs create constituencies by making the case for categorizing society in particular ways, and that those constituencies are then the platform not only for mobilization and collective action but also for their own leadership (Haslam et al., 2020).

8. IDENTITY IMPRESARIOSHIP: MAKING "US" MATTER

Leaders may succeed in becoming viewed as "one of us" and "doing it for us," and draw on skills of identity entrepreneurship to encourage followers to view them as providing leadership that helps the group in the pursuit of becoming who we are meant to become. However, to have *enduring* impact on society and the way it is organized, they have to work hard to ensure that the norms, values, and beliefs associated with shared self-understandings become concretized and embedded within societal institutions and social practice. Without this, a leader risks being seen as "all talk but no action," and their vision is likely to be viewed as little more than pie in the sky.

History provides many examples of leaders who understood the importance of concretizing and embedding shared social identity in structures and institutions. The Apostle Paul, for example, succeeded in building the Christian community through his vigorous promotion of rituals and practices that brought diverse communities together and allowed them to live out a shared religion. As theologians have argued, the major practical feat of Paul's leadership was to establish congregations within which he institutionalized a number of key rites, ceremonies, and practices (notably baptism and the Lord's supper, "the two main rituals of early Christianity"; Horrell, 2005: 129–130; see also Esler, 2003). As Horrell (2005: 110) observes:

The key social achievement of these community-forming actions [consisted] in the bringing together of many people into one body, the construction of a new form of corporate solidarity. Both rituals, baptism and the Lord's supper . . . communicate and reinforce a world-view in which the death and resurrection of Christ are the central event in a cosmic story—these events give meaning to the world, providing a fundamental hermeneutical orientation by which it is to be understood—and at the same time convey as the central theme of the Christian ethos the notion of a solidarity in Christ that transcends former distinctions.

More generally, this is the function of such things as political rallies, conferences and demonstrations that serve to bring people together and *enact* valued identities (see Haslam et al., 2020).

Importantly, identity impresarioship can be used to advance both benign and pernicious projects. Hitler, for example, understood that for Germans to embrace the shared self-understanding that he and his fellow fascists were looking to promote, it was necessary to engineer systems that enabled Germans to become active participants in the newly crafted national spirit. This was seen most potently in his appropriation of the Olympic movement in the staging of the 1936 “Nazi Olympics” in Berlin (Mandell, 2000; Reicher, 2020). On the one hand, these were an instantiation of Goebbels’ idea that “German sport has only one task: to strengthen the character of the German people, imbuing it with the fighting spirit and steadfast camaraderie necessary in the struggle for its existence” (cited in Rippon, 2006: 17). On the other hand, they were embraced as a global marketing exercise for the Nazi project, intended to bear testimony to the toughness of the German Volk and the vaunted superiority of Aryan ideals of racial purity that culminated in a crescendo of “emotional-patriotic impact” (Mandell, 2000: 199). Likewise, elsewhere Hitler not only promoted the production of movies that celebrated the Nazi cause (notably in Leni Riefenstahl’s *Triumph of the Will*, which portrayed him as descending from the heavens to lead a unified German nation), but also orchestrated massive rallies (notably in Nuremberg) that were choreographed so as to equate Hitler, the individual, with Germany, the category (Kershaw, 2001).

More generally, politicians are well aware of the importance of putting in place systems and structures that help to embed new shared self-understandings. In the United States, for example, considerable thought is put into the decoration of the Oval Office at the start of a new presidency (Brooks, 2011). Which previous presidents’ portraits should hang on the walls? Which symbols should be on display? What should be on the presidents’ desk? Similarly, the backdrop to leaders’ press conferences is often finely tuned to create precisely the right impression—with thought given to the composition of the audience, the flags, the slogans, the entrance music (Allegretti, 2021; Mandell & Martin, 2016).

On a larger scale the same identity-embedding objectives are achieved by erecting new monuments, initiating new commemorations, and inventing new rituals. Here, though, rather than engineering new self-understandings from scratch, leaders often treat existing understandings as “raw materials” that they can appropriate for new shared self-understandings. Indeed, leaders typically know their vision of “where we as a group are heading to” will be more persuasive if it is presented as aligned with, and seen to be a natural expression of, “where we as a group came from.” For example, Obama alluded to the motto “E pluribus unum” (out of many, one) written on all US currency, to invite Americans had unite under his leadership, thus appropriating America’s past for his vision of its future (Augoustinos & De Garis, 2012). Indeed, this is a key reason why commemorations and

FIGURE 22.1 The four components of identity leadership that are integrated within the social identity approach to (political) leadership (after Haslam et al., 2020)

celebrations of history (e.g., on Remembrance Day, on Labor Day) are often a critical site for leaders to engineer new visions of “our future”—visions of which they are prototypical.

A case in point here are museum displays and celebratory events and texts designed to immerse observers in history and give them a particular experience of it. It is telling, for example, that on the road to high office, presidents and prime ministers typically set out their vision in a heavily-marketed book that seeks to establish their identity credentials (e.g., Nelson Mandela’s *Long Road to Freedom*; Barack Obama’s *Dreams from my Father*; Donald Trump’s *Art of the Deal*; Boris Johnson’s *The Churchill Factor*). Critically, such activities inform prospective followers about “who we are,” what we should learn from the past, and accordingly what vision of the future we should endorse (e.g., one of peaceful cooperation or aggressive competition) (Figure 22.1). However, in the process they also set up the leader as the person who can deliver against that agenda by providing *identity continuity* between who we have been in the past, who we are now, and who we will be in the future (Haslam et al., 2021; Reicher, 2004).

9. CONCLUSION

We began this chapter with a critique of the heroic approach to leadership which conceives of leaders as exceptional individuals who are understood to possess an exceptional personality

and character that sets them apart from ordinary mortals. We then reviewed more contemporary leadership approaches that have been developed in social and organizational psychology and that seek to account for the context-dependence of leadership success and the subjectivity of perceived charisma. Significantly, these approaches generally recognize the importance of followership as a necessary accompaniment to leadership. Nevertheless, by construing this as the natural consequence of exposure to leaders with particular traits and styles, and hence seeing leaders' individual differences as the key reason why followers support them, these approaches sidestep the question of how leaders change in response to group circumstances, how people (voters) are *converted* into actively engaged followers (partisans), and hence how leaders and followers *co-produce* social and political change. Some of these ideas are captured in descriptions of transformational leadership, but the extant theory around this is mute as to how exactly this process works.

Another issue consistently sidestepped is that of *identity-based* subjectivity. For example, in research on authentic leadership (Avolio et al., 2004; Avolio & Gardner, 2005), followership is viewed as the product of leaders' capacity to be truthful to their inner self, but this neglects the fact that leader authenticity is perceived subjectively through the lens of shared (or non-shared) social identity (Steffens et al., 2016). Critically, then, as we have seen, it is social identity that ultimately binds leaders and followers together and that structures followers' experience of authenticity and other aspects of the leadership process (e.g., intelligence, morality, vision, fairness; Haslam et al., 2020).

Research into partisanship and affective polarization grapples with exactly the same issues. As authors commenting on the methodological individualism that pervades this literature have noted (Agassi, 1960; Mols & 't Hart, 2017), what is lost through a focus on individual differences are the *group processes* that shape group members' perceptions (Huici et al., 1997; Mols et al., 2009; Van Bavel & Pereira, 2018). In our view, then, the importance of social identity for all aspects of the leadership process is hard to overstate.

Although it has been a long time coming, there is evidence that this point is increasingly being recognized in various branches of political science. First, there is widespread consensus (a) that partisan polarization is an increasing relevant feature of Western democracies (McCarty et al., 2006), (b) that voters can be motivated by positive and negative partisanship (Caruana et al., 2015; Abramowitz & Webster, 2016), and, more importantly, (c) that this partisanship revolves around social identity rather than rational policy preferences (Campbell et al., 1980; Greene, 1999; Huddy et al., 2015; West & Iyengar, 2020). Second, there is growing recognition that elites and mass publics influence ("cue") each other (Feldman et al., 2012; Hooghe & Marks, 2005; Mols & Jetten, 2020), and that it is important to take group identities and their influence into account when seeking to understand the effects of framing messages and cultivated public sentiments (Mols, 2012). In practical terms, this means that political psychologists gauging voter attitudes have to come to grips not only with issues of geographical multilevel modelling (Steenbergen & Jones, 2002), but also with the fact that humans have multiple nested social identities to which politicians appeal. These, though, can easily be overlooked if research design is not attuned to these dimensions of the political process (Huici et al., 1997; Mols et al., 2009).

The new psychology of political leadership that is advanced in this chapter differs fundamentally from individualist approaches that have dominated and dogged the field to date in seeing the psychology of effective leadership as grounded in the social identity that a leader builds and advances with followers, rather than in his or her identity as an individual.

Moving beyond the idea that it is leaders' or followers' personality that is the key driver of effective leadership and group advancement, this approach helps us to appreciate that these things are always a matter of effective social identity management (Haslam et al., 2011; Steffens et al., 2014). In these terms, while the political scientist Harold Lasswell may have been correct to assert that politics is about "who gets what, when and how" (Lasswell, 1958), we would argue that when it comes to political leadership these things all hinge on the social identities that define the "who" of this formulation. Ultimately, then, it is typically the political leader with the most persuasive social identity narrative about "who we are" who wins the hearts and minds of voters, and who thereby gains control over who gets what, when, and how.

NOTE

1. As Adorno noted, "Personality is not to be hypostatized as an ultimate determinant. Far from being something which is given in the beginning, which remains fixed and acts upon the surrounding world, personality evolves under the impact of the social environment and can never be isolated from the social totality within which it occurs. [. . .] The conception of personality structure is the best safeguard against the inclination to attribute persistent trends in the individual to something 'innate' or 'basic' or 'racial' within him" (Adorno et al., 1950, 5).

PART IV

INTERGROUP
RELATIONS

CHAPTER 23

GROUP-BASED HIERARCHIES OF POWER AND STATUS

MAUREEN A. CRAIG AND L. TAYLOR PHILLIPS

GROUP-BASED identities, such as gender, ethnicity, religion, and many more, continue to shape people's life chances and outcomes and in many cases form the basis for group-based inequality. Indeed, group-based inequality has been increasing over the last decades in many countries worldwide (United Nations, 2020). Where inequality or disparity exist, so does hierarchy—the rank-ordering of individuals or groups based on some valued dimension(s) within human structures (e.g., organizations, societies; Magee & Galinsky, 2008, p. 5). Hierarchies are often structured around disparities in resources such as power (i.e., possessing more or less control over other people and resources), authority (i.e., legitimacy, right, or formal claim to control), status (i.e., esteem, respect, and admiration), or even cultural values (i.e., collective values and meaning systems; see Stephan et al., 2009; Zou & Cheryan, 2017). Given the ubiquity of group-based hierarchies and their intransigence, despite worldwide efforts to mitigate them in recent decades (United Nations, 2020), it is imperative to understand how individuals exist within and respond to group-based hierarchy.

This chapter examines the interaction between individuals and complex societal and political systems that generate group-based hierarchies of prestige, power, and privilege. Hierarchy is essential reading for political psychologists: merely existing within social hierarchies affects people's psychology and consequently, their propensity to engage in political action. Indeed, how people interact with hierarchical systems can inform not only whether, but also what kinds of actions members of different groups may take to alter or maintain existing hierarchies. How do people interact with existing group-based hierarchies? How do group-level motives impact action intended to alter or maintain hierarchy? What downstream consequences does this have for political action? The present chapter reviews and integrates contemporary and classic social scientific research to understand the political implications of individuals' position and experiences within group-based hierarchies, as well as their attempts to change or maintain such systems.

1. LEVEL OF ANALYSIS: GROUPS AND INDIVIDUALS

Status and power are theoretically separable and distinct bases of hierarchical differentiation. Power indicates control over valued resources and the ability to influence others,

whereas status indicates perceived respect and esteem, both of which can lead to greater influence over others (see Blader & Chen, 2012; Cheng et al., 2013; Magee & Galinsky, 2008; see also Fiske, 1993; French & Raven, 1959; Keltner et al., 2003; Thibaut & Kelley, 1959). Some theoretical traditions focus more on the precursors and consequences of social status (e.g., social identity theory; Tajfel & Turner, 1979), some focus more on power (e.g., social dominance theory, SDT; Sidanius & Pratto, 1999), and some view power as the source of status, explaining why at the group level these constructs are often highly conflated (status characteristics theory; Berger et al., 1972).

While there are literatures across several social scientific fields examining processes underlying and associated with individuals' experiences of *personal* power and status, we focus on how belonging to socio-demographic *groups* that vary in their level of influence over society (e.g., race, ethnicity, gender) affects individuals' experiences of and responses to hierarchy itself. The present chapter focuses on understanding how individuals respond to and are impacted by existing group-based hierarchies, in which power and status are not easily separated. Given that there is often a conflation at the group-level between power and status such that high-status groups tend to be powerful as well (and *vice versa*), this chapter focuses on individuals' membership in groups that are socially dominant (groups that are high in status and/or power in society) or socially marginalized (groups that are low in status and/or power in society; Magee & Galinsky, 2008). If a distinction between power and status is essential to understand a finding, we will use the terms high-status and low-status or high-power and low-power groups to clarify.

Of course, group membership is not the only driver of individuals' experiences with and response to group-based hierarchy. Ample variation exists within groups, as well as between groups. For instance, individual differences such as personality (e.g., Altemeyer, 1988; Bakker, Chapter 2, this volume; McFarland, 2010; Perry & Sibley, 2012), ideology and attitudes (e.g., Federico and Malka, Chapter 17, this volume; Jost et al., 2009; Tesler, 2016; Tesler & Sears, 2010), and core values (Ben-Num Bloom, Chapter 18, this volume; Sagiv & Roccas, 2021; Schwartz, 1994) also affect individuals' experiences of and responses to group-based hierarchies, as described in existing reviews. Here, we focus in particular on research cataloging the ways in which individuals' group membership—in relatively socially dominant versus socially marginalized groups—impacts individuals' experience of group-based hierarchy, and the political implications of such experiences. However, where relevant, we also highlight when individual differences might moderate the effects of group membership or even overwhelm group-based effects.

2. THEORETICAL EXPLANATIONS

Given the pervasiveness of group-based hierarchical systems, it is perhaps unsurprising that several theories have emerged seeking to explain why hierarchies exist (e.g., social dominance theory; Sidanius et al., 2017; Sidanius & Pratto, 1999) and persist (e.g., social justification theory; Jost, 2020; Jost & Banaji, 1994). The emergence of group-based hierarchies has been extensively covered in prior reviews, so we do not rehash this discussion (for recent reviews about the theoretical explanations for why hierarchies exist and the impact of group-based dominance, see Anderson & Kilduff, 2009; Cheng, 2020;

Mahadevan et al., 2016), but we provide a brief overview of several predominant social scientific theories.

Decades of theorizing and research have highlighted the role of group interests as one instigator of intergroup conflict (e.g., Duckitt, 1994, 2001; Esses et al., 1998, 2001; LeVine & Campbell, 1972; Sherif, 1967; Sherif et al., 1961). This work suggests that a motive to advance one's group's interests (e.g., by attaining resources) can lead to competition between different social groups and from this competition, hierarchy may emerge and perpetuate. Notably, realistic group conflict theory (LeVine & Campbell, 1972; Sherif, 1967; Sherif et al., 1961), a classic theory about the origins of intergroup conflict and prejudice, suggests that prejudice and conflict stem from competition over scarce resources and group interests. Specifically, this work (e.g., LeVine & Campbell, 1972; Sherif, 1967) suggests that if members of one social group experience or perceive threat from another social group to which they do not belong (i.e., an outgroup), this tends to heighten prejudice toward this outgroup. The instrumental model of group conflict (Esses et al., 1998, 2001), also highlights the role of perceived scarcity in group conflict and hierarchy maintenance. This model posits that perceptions of resource scarcity and salience of a potentially competitive outgroup together guide intergroup competition. Further, this model suggests that hierarchy itself (i.e., the unequal distribution of resources among societal groups) may facilitate the perception of limited or scarce resources, which then perpetuates group conflict and group hierarchy.

While research examining realistic group conflict theory most frequently considered competition between groups of equal status (see Sherif et al., 1961), the dual-process cognitive-motivational theory of ideology and prejudice (Duckitt, 1994, 2001) extended this theorizing to consider different forms of intergroups relations within hierarchical systems. For example, Duckitt (1994) posited that prejudice and intergroup conflict can result from both a threat-driven group defense motivation and a competitive motive to attain dominance, power, and superiority. These dual motivations highlight that a higher-status group's expression of prejudice toward a lower-status group need not necessarily be driven by perceived threats to one's group interests and resources, but could simply stem from motives to attain dominance.

This motive to attain group dominance is paramount to another predominate theory within political psychology, social dominance theory (SDT; Sidanius & Pratto, 1999; Pratto et al., 2006), which suggests that hierarchies emerge due to evolutionary pressures and distinguishes three types of hierarchical systems: age-based (in which adults have greater power than children), sex-based (in which men have greater power than women), and arbitrary-set-based (which encompasses the remainder of group-based hierarchies, including those based on race, ethnicity, or religion, for example). This term "arbitrary-set" is meant to highlight the social construction and non-universality of these hierarchies that are based on the most salient social distinctions within a given society. Classic SDT (Sidanius & Pratto, 1999; Pratto et al., 2006) suggests that individuals interact with hierarchy in one of two opposing ways: hierarchy-enhancing versus hierarchy-attenuating behavior. Hierarchy-enhancing behavior constitutes actions that serve to enhance or maintain the existing hierarchical arrangement, for example, expressing racial bias, supporting policies such as that serve dominant group interests (e.g., lowering the taxes of wealthy individuals), or opposing policies that would benefit marginalized group interests (e.g., affirmative action). Hierarchy-attenuating behavior, on the other hand, includes actions that serve to attenuate the existing hierarchical arrangement, for example, expressing egalitarianism, supporting

policies that serve marginalized group interests, or opposing policies that would benefit dominant group interests.

Social dominance orientation (SDO; Pratto et al., 1994) is understood as a fundamental motive underlying hierarchy-enhancing or hierarchy-attenuating behavior. SDO indicates an orientation toward or preference for group-based dominance and inequality (Ho et al., 2012), irrespective of the position of one's own group (ingroup) in that hierarchy (Pratto et al., 2006; Sidanius et al., 1994, 2017). People who score higher on SDO tend to support hierarchy-enhancing action, while those who score lower tend to support hierarchy-attenuation. The origins of the SDO motive itself are relatively understudied, but it has been theorized as a relatively stable, individual trait, passed down either biologically or environmentally by parents to children (Duriez & Soenens, 2009; Kandler et al., 2016; Kleppstø et al., 2019). However, predictable tendencies in which members of dominant groups in hierarchies (e.g., men, White Americans) on average score higher on SDO than do members of marginalized groups in group-based hierarchies (e.g., women, Black Americans) suggests that the social structure and group interests and motives also play a role in contributing to this individual difference orientation (Sidanius et al., 2017).

In addition to work considering the emergence of hierarchy, there is also research examining the question of how and why hierarchies sustain themselves. System justification theory (Jost & Banaji, 1994) provides one such explanation for why hierarchies are preserved, once established. This theoretical framework distinguishes three forms of justification that people may be motivated to engage in. Specifically, this work delineates ego-justification (driven by a motive to view oneself positively), group-justification (driven by a motive to view one's group positively), and system-justification (driven by people's desire to view the system or status quo in a favorable light, for example, as legitimate and fair). Given these proposed motives, among members of socially-dominant groups, all three of the motives should be often congruent with one another. In contrast, among marginalized groups, the group-justification motive may often conflict with the system-justification motive. For example, a desire to bolster and justify the status quo of persistent gender inequality in which women, on average, tend to earn less than men (Barroso & Brown, 2021) would require viewing such gender disparities as justified. Justifying the system and status quo in this way would be consistent with a motive to enhance or maintain men's high-standing, but would be counterproductive for a woman viewing her gender group (women) in a positive light. One intriguing aspect of system justification theory is that it seeks to explain when and why people who are socially-marginalized may sometimes act in ways that sustain their own subjugation (Jost, 2020; Jost & Banaji, 1994; Jost et al., 2004).

Complementing the psychological theories detailed above, status characteristics theory (SCT; Berger et al., 1972) stems from a sociological tradition and seeks to describe the process through which group memberships (e.g., race, gender, and education level) become associated with differential resource and performance expectations, and thus, how these memberships come to provide status and create stable hierarchies (Berger et al., 1972; Ridgeway, 1991; see also expectation states theory, Wagner & Berger, 1993 for a historical review). Expectations serve as a key mechanism for hierarchy stability in this theory. To the extent that individuals learn to expect more (versus less) valuable contributions from individuals of different groups, they then will pay more (versus less) attention, deference, and respect to those individuals. In turn, targets from whom more is expected are given more opportunity to confirm these expectations, while those from whom less is expected

are given little opportunity to disconfirm these low expectations. Considered in tandem with the psychological phenomenon of self-fulfilling prophecies (Rosenthal & Jacobson, 1968), in which someone's expectations about another person lead that person to act in ways that confirm preconceived notions, it is little mystery why this process could entrench hierarchies and the status quo.

Critically, expectations about others' value are generated not simply from idiosyncratic initial experiences with specific individuals, but also draw from pre-existing associations and stereotypes based on basic social categories (so-called diffuse status characteristics such as gender or race; Berger et al., 1972). Thus, before an individual-level interaction even occurs, *a priori* expectations due to group stereotypes can direct the likely pattern of power and prestige hierarchy that will emerge within an organization. Given these dynamics, the rank-order of groups within a hierarchy tend to remain stable over time. Indeed, this proposition has been demonstrated not only empirically and theoretically, but with mathematical modeling (e.g., Berger et al., 1977; Fisek, 1974; Foschi & Foschi, 1979).

3. OVERVIEW

The ways in which people can interact with hierarchical systems will provide the organization of this chapter. We begin by outlining when and why people may take action to influence an existing group-based hierarchy. First, people may seek to *maintain* the existing hierarchy, protecting the position of dominant groups and maintaining the distance between those at the bottom and top. Second, people may also seek to *enhance* the existing hierarchy, improving the position of dominant groups and increasing the gap between those at the bottom and top. Third, people may seek to *mitigate* group-based hierarchies, improving the position of marginalized groups, reducing the position of dominant groups, and decreasing the distance between the bottom and top. And fourth, people may seek to *rearrange* group-based hierarchies, changing the positions of various groups without necessarily affecting the amount of hierarchy or the distance between the bottom- and top-ranked groups. After detailing this work examining when people seek to influence hierarchical systems in these different ways, next we will discuss research on how people *react* when the hierarchy is perceived to be under these different states (e.g., maintained and stable, enhanced, mitigated, or rearranged). Finally, we end by considering open questions and opportunities for future work.

4. MAINTAINING OR ENHANCING GROUP-BASED HIERARCHIES

People may act in ways that serve to maintain or even enhance hierarchical systems. We begin with the broad literature that examines the circumstances in which individuals may seek to maintain hierarchy and the status quo, before considering the less empirically examined question of when people may seek to make hierarchies more extreme.

4.1. Maintenance of Group-Based Hierarchies

One of the core areas of investigation in system justification theory (see Jost, 2020, for an overview) is in understanding how and why people may seek to maintain the often inequitable and hierarchical social, economic, and political status quos. Research examining system justification motivation has found that it can manifest in a number of different ways (e.g., in terms of stereotyping, ideology, attributions) and occur implicitly (e.g., nonconsciously) as well as explicitly (e.g., Jost et al., 2002; Kay & Jost, 2003). Further, this work has found that perceiving that the existing system or one's worldview is under threat can increase system justification. As an example, perceived threats to the system (e.g., manipulated via a passage that directs criticism toward the current social system or not) can lead individuals to come to its defense and express system bolstering attitudes (Kay et al., 2005).

Other recent work has tested whether feelings of powerlessness can activate a system justification motive and lead to perceiving the existing social system as legitimate. Across several experiments (van der Toorn et al., 2015), undergraduates were randomly assigned to complete an essay task in which they were asked to detail an event in their lives in which either they had power over someone else (high power condition) or someone else had power over them (low power condition; a common perceived power manipulation, see Galinsky et al., 2003) and then completed items assessing system justification and perceptions that several social inequalities are legitimate. Results revealed that in contrast to what a self-interest perspective might predict—but consistent with system justification theory—participants who were induced to feel powerless (versus powerful) were more likely to report that the existing societal status quo was fair and legitimate (van der Toorn et al., 2015). Furthermore, induced feelings of powerlessness (versus powerfulness) led to reports that the unequal distribution of wealth, the gender pay gap, and disproportionate incarceration rates of Black Americans were more legitimate (van der Toorn et al., 2015). Overall, work within the system justification theoretical tradition suggests that the maintenance of an inequitable status quo can be contributed to by people's motives to see the system as just and fair, including among those who may be marginalized by the current system.

Turning to sociology, while the original work on status characteristics theory was formulated to understand bounded interactions within dyadic or small team settings, later research expanded to consider how the emerging hierarchies in these organizational contexts might affect future interactions in other teams and as a result, serve to maintain group-based hierarchies (Berger et al., 1989). For instance, Ridgeway and colleagues (e.g., Ridgeway, 1988; Ridgeway & Berger, 1986) demonstrated how societal-level hierarchies create *a priori* expectations regarding characteristics like race and gender, and, in turn, these expectations can create a self-fulfilling pattern during interpersonal interactions, which ultimately reinforce the original societal-level hierarchy. Moreover, Ridgeway (1991) argues that these original status expectations themselves come into existence via association with differentiated resources. That is, if an inequality exists and people have differential access to resources, depending on group membership, this in turn leads perceivers to associate members of those groups with more or less resources (see also, "social role theory"; Koenig & Eagly, 2014).

Indeed, recent empirical evidence supports this point and finds evidence of race-status associations in which White Americans are mentally linked with the concept of high

status and Black Americans with the concept of low status (Dupree et al., 2021); consistent with Ridgeway's (1991) theorizing, the authors (Dupree et al., 2021) suggest that these associations may occur due to observation of racially distributed jobs, among other potential explanations. Given this, economic, political, and other social structures that generate resource hierarchies (i.e., differential group access to material and symbolic resources) can become legitimated and reinforced via expectations. As an example, a policy that leads men to receive higher wages than women may then generate an expectation that men have more resources than women, in turn granting status advantage to men, ultimately reinforcing the initial resource discrepancy.

A final theoretical tradition that speaks to hierarchy maintenance is social dominance theory (Pratto et al., 2006; Sidanius & Pratto, 1999; Sidanius et al., 2017). Research seeking to understand how social dominance orientation (SDO) is linked to social attitudes reveals that individuals who are more supportive of hierarchy and anti-egalitarian (i.e., higher in SDO) express attitudes and act in ways that would serve to maintain the hierarchy (Ho et al., 2015; Sidanius & Pratto, 1999). For example, high-SDO individuals express prejudice against marginalized groups and express exclusionary attitudes toward those who would threaten existing hierarchies (e.g., marginalized groups seeking to gain in status; see Craig & Richeson, 2014c; Thomsen et al., 2008).

This theory also highlights that people can be drawn to different institutions depending on their level of SDO, and playing a role within the institution can itself shape someone's levels of SDO (Sidanius et al., 2004). Specifically, those high in SDO are drawn to hierarchy-enhancing institutions whereas those low in SDO are drawn to hierarchy-attenuating institutions (Sidanius et al., 1996); as an example, among students, higher SDO scores predicted interest in careers like prosecutor or police officer, whereas lower SDO scores predicted interest in careers such as civil rights lawyer. Once in those settings, however, socialization into a hierarchy-enhancing institution can increase attitudes that serve to maintain the hierarchy. For example, White police officers developed more hostile attitudes toward Black Americans across their first 18 months of training, whereas Black officers developed *less* hostile attitudes towards Whites in that same time (Teahan, 1975). Furthermore, SDO can predict electoral behavior, as a nationally representative survey revealed that the extent to which voters' SDO increased from 2012 to 2016 predicted a shift away from the Democrat Hillary Clinton and toward the Republican Donald Trump, a candidate whose campaign rhetoric focused on a return to the status quo of the past (e.g., with the slogan "Make America Great Again"; Mutz, 2018).

While the above work suggests some people may have motivation to maintain the hierarchy and current status quo, people are also sensitive to others' opinions of them and strive to shape others' views of them and be viewed well (e.g., impression management; Goffman, 1959). Given cultural shifts in the United States over the last decades toward less acceptability of certain forms of prejudice (including racial prejudice; Crandall et al., 2013; although, see Crandall et al., 2018), those who support dominating outgroups (e.g., high-SDO individuals) may also attempt to do so in less overt ways. This shift toward less perceived acceptability of explicit, overt racial bias can also be seen in how the very ways in which social scientists attempt to measure racism have changed over time (see Kinder, Chapter 27, this volume).

Similarly, recent work finds that in addition to being predictive of the expression of explicit prejudice in the service of maintaining hierarchy, SDO is also related to less overt

expressions of hierarchy maintenance. For instance, while White Americans high in SDO *privately* support White political candidates who report that their racial identity is a central aspect to who they are, there was less *public* political support for these White candidates out of concern that they might provoke racial minorities (Jun et al., 2017). Furthermore, dominant group members who support hierarchy may attempt to appease marginalized groups by sacrificing small concessions in order to maintain the overall hierarchy (Chow et al., 2013). In particular, if the hierarchy is less stable or marginalized groups are seen as more angered, those high in SDO are *less* opposed to policies that would redistribute resources and opportunity (e.g., affirmative action). Indeed, this work (Chow et al., 2013) revealed that high-SDO White Americans only expressed strong opposition to redistributive policy if their concern about hierarchy stability was allayed, suggesting that those high in SDO may generally view hierarchy as stable, but that concerns over system stability can mute usual tendencies toward publicly expressing support for hierarchy maintenance.

4.2. Enhancement of Group-Based Hierarchies

Interestingly, whereas classic theorizing within the SDT tradition emphasizes hierarchy-*enhancing* motivations (Sidanius & Pratto, 1999), empirical work on SDO often focuses on hierarchy-*maintenance* outcomes. For example, opposition to a policy that seeks to reduce hierarchy, such as affirmative action, would serve to maintain, but not necessarily enhance hierarchy. That is, SDO tends to predict the support of the status quo (maintaining hierarchy) and opposition to reducing inequality, rather than strictly support for making the hierarchy more *extreme* (i.e., enhancing hierarchy). While much work referenced thus far, spanning disciplines and theoretical traditions, has considered the question of when people support maintaining hierarchies, one may also seek to make a hierarchical system *more unequal*, or be motivated toward hierarchy-enhancing action.

Work highlighting the motivational pull of maintaining positive group esteem suggests that one can protect positive views of the ingroup by vying for group status within the hierarchy (Tajfel & Turner, 1979). This process, known as social competition, is posited to be most likely to occur if group boundaries are impermeable and the hierarchy is viewed as unstable (Tajfel & Turner, 1979). Further, in unstable hierarchies, people desire not only stability, but a dominant position within a more stable hierarchy (Caricati, 2012). Given that individuals do indeed often actively seek to enhance their own personal status (Anderson et al., 2015) and attempt to maximize their personal gains (Kelley & Thibaut, 1978; see Thielman et al., 2021, for a review), it is reasonable to suspect that similar processes may operate at the group level. Indeed, recent work has identified that desire for status is a fundamental human motive (Anderson et al., 2015; Kim & Pettit, 2019; Mahadevan et al., 2019), implying that humans are driven to seek increasing status.

Original formulations of SDT (Sidanius & Pratto, 1999) emphasized hierarchy-enhancing motives, rather than hierarchy maintenance alone. Perhaps representing a return to this tradition, recent research on SDO has begun to explore the idea that high-SDO individuals (both those belonging to dominant and marginalized groups) can have motivation to dominate outgroups. Specifically, emerging work on SDO hints at desires among high-SDO people to achieve *more* hierarchy (Kteily et al., 2017, 2019; Lucas & Kteily, 2018).

Interestingly, this recent work demonstrates that SDO not only relates to preferences for the ideal amount of hierarchy, but even shapes how people *see* the existing hierarchy in the first place. SDO is predictive of people's processing and memory for hierarchy itself, which in turn can shape desires to enhance (or mitigate) hierarchical structures. In a series of creative experimental studies, Kteily and colleagues (2017) showed that, if presented with the same visual representation of a hierarchy (e.g., human stick figures arranged in a pyramid shape that varied in the steepness of the slope to manipulate level of hierarchy), individuals scoring higher in SDO misremembered the stimulus as having shown *less* hierarchy than was accurate, whereas those lower in SDO misremembered *more* hierarchy than was accurate. The authors (Kteily et al., 2017) posit a motivated information processing account (e.g., Balcetis & Dunning, 2006) and suggest that this pattern of perception is driven by a desire to justify one's orientation toward hierarchy. That is, those motivated to enhance hierarchy (those high in SDO) perceived less hierarchy than was actually present, which should justify seeking more hierarchy. In contrast, those motivated to attenuate hierarchy (low-SDO individuals) perceived more hierarchy than was accurate, which presents the justification for aims of reducing hierarchy. Thus, this work suggests one's preference for hierarchy can shape perception and memory for hierarchies themselves. These perceptual differences can impact downstream political preferences: the more people supported group-based hierarchy, the less they perceived a novel unequal society as hierarchical, which predicted less support for redistributive policies intended to reduce the inequality and hierarchy (Kteily et al., 2017).

In addition to basic perceptual biases, there are biases in the degree to which individuals with varying levels of SDO attribute harm, depending on whether an action affects dominant or marginalized targets (Lucas & Kteily, 2018; Waldfogel et al., 2021). For example, Waldfogel et al. (2021) demonstrated that support of SDO relates to individuals' attention to hierarchy: whereas people more supportive of egalitarianism (lower-SDO) are more likely to notice and accurately remember social inequality that negatively impacts marginalized groups, more anti-egalitarian (higher-SDO) individuals are more likely to notice when inequality disadvantages dominant groups (e.g., men; see also Lucas & Kteily, 2018). Goudarzi and colleagues (2020) also find that people's ideology regarding whether the economic system is fair (i.e., economic system-justification) predicted both self-report and physiological responses to economic inequality. Particularly, this work revealed that exposure to suffering stemming from economic inequality (e.g., video clips depicting people experiencing homelessness) triggered *less* negative emotion, as indexed by facial muscle activity and skin conductance patterns signifying negative affect (e.g., furrowed brows) and arousal (e.g., sweatiness), among those who highly (vs. lowly) justified the current economic system. Taken together, this work demonstrates that people's experiences of and perceptual processes regarding inequality differ depending on ideology (e.g., preference for hierarchy, support for egalitarianism, and justification of the status quo). To the extent that individuals perceive and experience hierarchy differently, they may reach different conclusions regarding which reparative actions are warranted. For example, to reach one's preferred state of hierarchy, if one is low in SDO and tends to perceive the presence of more hierarchy (particularly hierarchy that affects marginalized groups), they may prefer hierarchy-mitigating action, but if one is high in SDO and tends to perceive less hierarchy (unless the hierarchy harms socially-dominant groups), they may prefer hierarchy-enhancing action.

New research (Gutierrez & Unzueta, 2022) with largely White samples has revealed that participants' SDO levels predicted their liking of and support for hiring a job candidate who had explicitly discriminated against Black Americans or instituted policies that decreased the number of Black hires (hierarchy-enhancing behavior). Other recent work (Kachanoff et al., 2020) that has examined when hierarchy enhancement may occur reveals that perceptions that other groups are trying to control White Americans (termed *collective autonomy restriction*) predicts White Americans' support for working together with others of their racial group to further racial group interests. If enacted, these types of behaviors would, at minimum, serve to maintain the racial hierarchy and further could easily serve to enhance and accentuate the hierarchy.

While this new research is intriguing, much more work is necessary to separate the circumstances that may elicit hierarchy maintenance (e.g., opposition to policies such as affirmative action that would reduce hierarchy) versus hierarchy enhancement (e.g., support for policies such as reducing tax rates of the wealthy that would exacerbate hierarchy). Overall, whereas ample empirical research has considered individual efforts to protect and maintain the current hierarchy, less work has considered when individuals seek to *increase* inequality and stretch the group-based hierarchy itself.

5. MITIGATING OR REARRANGING GROUP-BASED HIERARCHIES

Research has also considered the different motivations that may drive marginalized and dominant groups to reduce group-based hierarchy. First, we consider the perspective of members of marginalized groups and when they may seek to take action to mitigate existing group-based hierarchy. Then, we consider the perspective of members of dominant groups and the circumstances in which they may seek to mitigate group-based hierarchy, even at the expense of their group's dominant position. Finally, we turn to a related, but understudied, form of interacting with hierarchy: rearranging the order in which the groups are positioned.

5.1. Hierarchy Mitigation Enacted by Marginalized Groups

Much of the literature examining when people seek to reduce intergroup hierarchy focuses on understanding when members of marginalized groups work to improve their own group's position through a variety of methods—from voting and engaging with electoral politics, to protest and collective action. Collective action is often defined as behaviors enacted by individuals as “psychological group members” with the goal of improving their group's conditions (van Zomeren, 2013; van Zomeren et al., 2008; Wright et al., 1990; see also van Stekelenburg & Gaidyte, Chapter 26, this volume). While most frequently examined in the context of social protest, this definition of collective action is inclusive of traditional social protest actions such as petition signing and actively protesting, but also electoral participation such as voting (van Zomeren et al., 2018). Given the focus of this

literature on predicting when people who psychologically identify with a group act on behalf of it, collective action research typically includes samples of people who are members of the group seen as detrimentally impacted by a form of inequality (e.g., Black Americans' efforts to reduce anti-Black racism).

As noted above, acting to pursue group interests could take the form of acting within existing political systems to seek to improve one's group position. For example, scholars have argued that to leverage their political strength as a numerical demographic minority group in a two-party political system, Black Americans prioritize group solidarity in party politics to form a stronger voting bloc (White & Laird, 2020). While ideologically diverse, over 80% of Black Americans self-identify as Democrats and this engagement with party politics serves racial group interests by increasing the likelihood of the party responsiveness and prioritization of racial group issues (White & Laird, 2020). Thus, one common form of action that marginalized group members may take to attempt to mitigate hierarchy is by working through the political system and institutions as they currently exist (e.g., voting in elections).

Another form of hierarchy-mitigating action that marginalized groups could pursue is to seek to change the very systems viewed as unjust. Research on collective action highlights that members of marginalized groups may pursue social change to improve their group's position within a hierarchy. Collective action has been investigated by political psychologists across multiple countries (e.g., within the United States: Chong, 1991; Selvanathan et al., 2018; Northern Ireland: Noor et al., 2008; Israel/Palestine: Hasan-Aslih et al., 2020) and domains (e.g., racial inequality: Selvanathan et al., 2018; gender inequality: Duncan, 1999; sexuality-based inequality: Techakesari et al., 2017). Across these varied social contexts, there is broad consistency in terms of the psychological processes that spur action towards social change. Particularly, this work highlights that identification with the affected group is a crucial precursor to feeling a sense of group-based injustice, which predicts support for acting collectively on behalf of that group (Stürmer & Simon, 2004, 2009; Wright et al., 1990, van Zomeren, 2013; van Zomeren et al., 2008). Generally, individuals are more likely to support or engage in social change action, if the intergroup hierarchy is perceived as unjust, if they identify with the marginalized group, and perceive that social action may be effective (see Van Zomeren et al., 2008, 2012). In addition to these precursors to action, perceived personal benefits may contribute to engaging in collective action. Specifically, acting as an activist can afford reputational benefits (Chong, 1991) and engaging in collective action can enhance one's status within one's own group (in addition to the possibility of enhancing one's ingroup's status in the hierarchy; Willer, 2009). As such, multiple psychological and relational processes contribute to individuals' decisions to engage in social change action.

While the above work considers when people act to improve their own group's position in a hierarchy, research has also examined the question of when people seek to improve the social position of a group to which they do not belong. This may take the form of solidarity, in which members of one marginalized group view their own group's experiences as aligned with those of another marginalized group (e.g., Black and Hispanic Americans may perceive that the two groups' discrimination experiences are similar, perhaps due to shared status as "racial minorities") and act to increase that outgroup's status (Craig & Richeson, 2012, 2016; Vollhardt et al., 2016). Specifically, solidarity represents advocacy on behalf of others perceived to share common cause, similar experiences, or broader inclusive group membership (Cortland et al., 2017; Craig & Richeson, 2016; Louis et al., 2019; Sirin et al.,

2016; Subašić et al., 2008; Thomas et al., 2009). As an example of solidarity in action, “The Coalition for Harmony in Monterey Park” movement in the 1980s brought Asian Americans and Hispanics together to fight a resolution that was perceived as discriminating against both Asian and Hispanic immigrants (e.g., the resolution would make English the official language and require English-only business signs; Horton, 1992).

Prior research suggests that political solidarity is more readily activated in contexts where different groups’ experiences and interests are seen as shared or similar (e.g., Cortland et al., 2017; Craig & Richeson, 2012, 2016). For example, a series of laboratory experiments with Hispanic and Asian American participants revealed that reading about the discrimination faced by one’s own racial group (anti-Hispanic and anti-Asian racism, respectively) led to the expression of more positive automatically-activated and self-reported attitudes toward Black Americans and that this increased positivity was statistically mediated through increased perceived similarity (Craig & Richeson, 2012). Similarly, in a national survey experiment (Sirin et al., 2016), Black and Hispanic Americans were more likely than White Americans to support pro-civil rights policies and actions regarding minority detainees and this effect appeared driven by greater group empathy. Overall, members of marginalized groups may support and seek to reduce hierarchy by improving their own group’s marginalized position (i.e., ingroup collective action) or the position of another marginalized group (i.e., solidarity; for further discussion, see Pérez & Vicuña, Chapter 25, this volume).

5.2. Hierarchy Mitigation Enacted by Dominant Groups

Of course, it is not only members of marginalized groups who might seek to mitigate a group-based hierarchy. For example, in research utilizing largely White samples, exposure to a job candidate who had a history of enacting policies that *increased* Black representation (a hierarchy mitigating action) led to more support for the candidate among those who scored lower (rather than higher) in SDO (Gutierrez & Unzueta, 2022). Similar to marginalized groups, perceiving that the current hierarchy is inequitable and unjust predicts dominant group members’ support for mitigating it as well (Leach et al., 2002; Phillips & Lowey, 2018; Radke et al., 2020; Tropp & Barlow, 2018). While this may run counter to group interests, a recent Pew Research Center poll found that, on average, 56% of White Americans report that being White helps in getting ahead in the United States (Menascé Horowitz et al., 2019). These beliefs about ingroup privileges are moderated by partisanship. For example, if that same Pew poll is broken down by political party, 78% of White Democrats reported beliefs about White racial advantages whereas only 38% of White Republicans reported similarly.

The literature on allyship focuses on understanding the circumstances in which members of a socially dominant group support action to reduce social-disparities that benefit their own social group (e.g., Whites’ support of reducing racial inequality). Specifically, allyship refers to the context in which members of a group that is socially dominant in a domain support action to reduce the disparities that relatively benefit their own group in this domain (see Craig et al., 2020; Louis et al., 2019). This context is particularly interesting from a group interest perspective, as members of the dominant group who seek to reduce hierarchy that benefits their ingroup are acting counter to group interests. This allyship literature suggests, perhaps counterintuitively, that certain forms of identification with one’s

dominant group identity can predict political engagement in support of improving the outcomes of a marginalized outgroup (Curtin et al., 2015; Iyer & Ryan, 2009).

Importantly, on average, reporting that one's dominant group identity is central or important to one's sense of self (common ways of measuring "identification") tends to predict support for maintaining or accentuating one's high-status place in the hierarchy (e.g., Jardina, 2019; Lowery et al., 2006). However, the perceived centrality or importance of one's identity (often called being "lowly identified" or "highly identified") is just one element of the multifaceted construct of social identification (see Ashmore et al., 2004). Recent work examining the different ways in which dominant group identification can manifest have revealed a more nuanced picture with intriguing implications for how dominant group identity may both facilitate or hinder hierarchy-mitigating action, depending on the lens through which one views the hierarchy. Specifically, this work (e.g., Croll, 2007; Goren & Plaut, 2012; Knowles et al., 2014) suggests that highly identifying with a dominant social group could either predict hierarchy-mitigating action or hierarchy-maintaining action, depending on how one views the hierarchical system itself and one's position within it.

For example, an analysis of a nationally representative data set found that the subgroup of White Americans who reported that their racial identity was "very important" to them expressed polarized responses on social issues (Croll, 2007). Highly identified White Americans were more likely to indicate *both* hierarchy-challenging and hierarchy-maintaining explanations for racial disparities, compared with White Americans who identified less strongly with their racial group (Croll, 2007). In another study (Goren & Plaut, 2012), White participants were asked to write about their racial identity and the research team coded the essays on whether participants (a) did not strongly identify with their ethnicity ("weakly identified"), (b) viewed their ingroup as a source of pride ("prideful" identification), or (c) acknowledged racial privileges ("power-cognizant" identification). White Americans rated as "prideful" or "power-cognizant" reported that their race was important to them at statistically equivalently high levels, but "power-cognizant" White Americans reported more positive attitudes toward diversity than those with a "prideful" identity (Goren & Plaut, 2012). This work highlights that viewing one's identity as central and important to one's life and experiences is distinguishable from the regard one feels towards one's group (see also Luhtanen & Crocker, 1992; Sellers et al., 1997) and that these different aspects of identity may interact to guide responses to group hierarchy.

Taken together, this work on White racial identity suggests that dominant group members who seek to mitigate the hierarchy may identify with their socially dominant ingroup but, importantly, identify in a way in which they critique the existing power structure and perceive their group to possess unearned societal privileges and power (Curtin et al., 2015, 2016; Goren & Plaut, 2012; Ostrove & Brown, 2018). The combination of these identity processes can facilitate support for dismantling hierarchical systems perceived as unjust (Knowles et al., 2014). With this form of "power-cognizant" dominant group identification, perceptions that their group has privileges in society as well as criticism, rather than legitimization, of the status quo and hierarchy are essential components that lead allies to pursue hierarchy-mitigating action (Knowles et al., 2014; Ostrove & Brown, 2018). It is notable that the existence of allies and egalitarian dominant group members challenges strong group interest theoretical accounts; however, in a later section we will introduce another route through which people who belong to a socially dominant group may support

hierarchy-mitigating action that does not require such explicit focus on relinquishment of group advantages.

Critiques of allyship. Whereas emerging work in psychology on allyship has emphasized the motivations that may spur dominant groups to “relinquish their privileges” (Brown & Ostrove, 2013), other work critiques that this perspective overemphasizes altruism among the dominant group. Recent scholars have theorized that dominant group allies also may be motivated to enact allyship due to ulterior goals focused on supporting oneself or one’s ingroup (Radke et al., 2020) or only if their own interests converge with marginalized groups (Bell, 1980; see also Acemoglu & Robinson, 2006). A strong interest-convergence account posits that any actions taken by the dominant group, even those that may superficially appear morally driven, are actually designed to serve the dominant group’s interest (Bell, 1980; Chow et al., 2013).

This perspective and self-focused motives are consistent with the appeasement motives highlighted in work examining circumstances in which dominant group members may show superficial support for redistributive policy in order to prevent the hierarchy from being destabilized (Chow et al., 2013). Similarly, Radke and colleagues (2020) posit that dominant group members who are more highly identified and hold social action goals that focus on the ingroup are more likely to engage in dependency-oriented help as well as enacting public, rather than private, action. A dominant group ally offering dependency-oriented help takes agency away from the marginalized group, which serves to reify the intergroup hierarchy (Nadler, 2002; Nadler & Halabi, 2006; Nadler et al., 2009). In contrast, an ally offering autonomy-oriented help (i.e., help that supports the marginalized group’s agency and independence) challenges the hierarchy and empowers the targeted group. From this perspective, what at first blush might seem to be hierarchy mitigation or the relinquishing of group-based dominance may yet serve to bolster the current hierarchy, depending on what form the aid takes.

Superordinate or “common ingroup” identity (e.g., as “Americans”; Gaertner et al., 1996) could also spur interest alignment, leading dominant groups to feel more positively and support improvements for the marginalized group in the interest of the whole, under certain conditions. For example, Transue (2007) experimentally manipulated whether White Americans were asked about how close they feel toward their racial group (subgroup identity prime) or toward Americans (superordinate identity prime) and found interesting effects particularly among those who reported feeling close to the primed identity. Whereas White Americans who felt close to their ethnic group expressed more support for tax increases to improving public schools than support for educational opportunities for minorities, this difference in policy support was statistically indistinguishable among those who felt close to other Americans (among those primed with a superordinate identity).

The fact that it was only those feeling close (versus not close) with a superordinate identity who expressed support for hierarchy-mitigating policy is an important caveat. Attempts to garner hierarchy mitigation and social change through superordinate identification alone are likely to fail, given the substantial amount of research finding that focusing on commonalities with outgroup members can elicit feelings of positivity and intergroup harmony, but can ironically *reduce* the likelihood that people see group-based inequality and, in turn, support social change (Saguy, 2018; Saguy et al., 2009, 2016; see also Dixon et al., 2010, 2012).

Regardless, even if dominant group members perceive interest convergence, this account would suggest that they would be less likely to support hierarchy mitigation if their interests begin to diverge from those of marginalized groups. Moreover, dominant groups may also attempt to reclaim superordinate identities by re-excluding marginalized groups from this identity (e.g., Danbold & Huo, 2021). Together, these patterns suggest that, at times, dominant groups' hierarchy mitigation action may serve to support their own interests, which align with marginalized group interests at the moment, but may be unlikely to be long-lasting.

Dominant group members and solidarity. While it is often studied as such, allyship is not the only pathway that may lead people who belong to a socially dominant group to support hierarchy-mitigating action (Craig et al., 2020). Indeed, just as is often discussed with members of groups who are marginalized in similar domains (e.g., Black and Hispanic Americans), members of the dominant group in a domain can connect their own experiences with inequality in another arena with the experiences of a marginalized outgroup. For example, a White American woman may seek to take action to mitigate the racial hierarchy by enacting allyship (driven by perceiving her racial privileges) as well as through solidarity (driven by perceived connections between sexism and racism). A key distinction between allyship and solidarity is whether individuals engage in social change through the lens of identifying with a socially marginalized identity (solidarity) or with a socially dominant group identity (allyship; Craig et al., 2020). Perceptions of shared discrimination experiences can spark solidarity (feelings of similarity and common cause) toward an outgroup perceived to face injustice among people who are marginalized within the same domain as the outgroup or from members of the group that is socially dominant in the domain. For example, both White and Hispanic Americans may express solidarity with Black Americans due to a perception of having shared discrimination experiences, but these perceived shared experiences could be along different dimensions of identity.

Recent theoretical work has begun to consider this question of how belonging to different social groups may influence motivations and support for different forms of social action to achieve hierarchy change (e.g., see Craig et al., 2020; Radke et al., 2020; Selvanathan et al., 2020). There is limited relevant empirical examination, however, particularly for understanding how the possession of multiple social identities influences support for hierarchy change. Given that individuals hold multiple, intersecting social identities (Cole, 2009; Kang & Bodenhausen, 2015; Remedios & Snyder, 2015), belonging to a socially dominant group in one dimension does not preclude facing discrimination along another dimension (e.g., Black men are members of a socially dominant gender group, but a marginalized racial group).

Recent experimental work finds that if people consider social disparities that advantage one of their group identities, they report facing greater discrimination due to their other identities as well as greater support for working with oppressed outgroups to pursue common cause (Brown & Craig, 2020). For example, among racial minority undergraduates from upper-income family backgrounds, considering class-based inequality led to greater reports that they experience discrimination due to their other social identities (e.g., reporting higher levels of racial discrimination). In another study conducted with heterosexual Americans, reading an article about discrimination faced by gay Americans led to reports that the social groups participants belonged to (ingroups) faced more discrimination and,

further, expressed greater support for the notion that different oppressed groups should work together (Brown & Craig, 2020).

This research suggests that considering a form of inequality in which one is a member of the socially dominant group (e.g., racial inequality for White women, class inequality for upper-income racial minorities, or sexuality-based inequality for heterosexuals) can heighten perceptions of discrimination faced due to one's other identities. This greater salience of ingroup discrimination in response to information about an outgroup's inequality could reasonably either spark solidarity (due to perceived shared experiences) or drive a wedge between members of different social groups (due to competitive victimhood processes; see Young & Sullivan, 2016; Vollhardt, 2020). Current research has not yet determined the circumstances in which each of these different downstream consequences may occur.

Research also finds that perceiving that one has faced discrimination in one domain can sensitize people to perceiving their group-based *privileges* along another domain (see Rosette & Tost, 2013). In samples of full-time working professionals, White women and racial minority men were more inclined than White men to report that their organization advantages White people and men, respectively, and this was particularly the case if they felt they were not able to thrive and be successful in their current job (Rosette & Tost, 2013). For example, White women were more likely than White men to report personal experiences with gender-based discrimination, which predicted perceptions that men have group-based privileges and, subsequently, perceptions that Whites have racial privilege (again, particularly among women who reported that they were moderately, but not highly, successful; Rosette & Tost, 2013). Taken together with the above work, this research finds that people can, at times, perceive connection among the different forms of social inequality and group-based hierarchies and that perceiving discrimination along one dimension can facilitate awareness or perception of group-based advantages and disadvantages in other domains.

As another example, research has found that presenting information about racism to heterosexual racial minorities can evoke a derogation effect, with less positive attitudes toward lesbians and gay men and less support for policies that would benefit sexual minorities (Craig & Richeson, 2014a). Yet recent research reveals that highlighting similarities in discrimination experiences can lead to an opposite pattern. Specifically, highlighting connections between past racial discrimination and recent forms of discrimination against sexual minorities (e.g., in terms of marriage laws that have historically targeted both groups) increases heterosexual racial minority group members' support for political positions that would benefit sexual minorities (e.g., support for legalizing same-sex marriage or adoption rights; Cortland et al., 2017). That is, despite being members of the socially-advantaged sexuality-based group, perceptions of shared discrimination due to one's racial minority group membership spurred empathy and solidarity (see also Sirin et al., 2016).

Overall, this work suggests that it may be useful to disentangle the type of psychological process underlying hierarchy mitigation (e.g., allyship, solidarity, ingroup collective action) from individuals' social group membership and, instead, focus on how people view their identities in relation to a form of inequality to determine which underlying process leads to social change action (see Craig et al., 2020). While social change may be jointly sought both by members of socially dominant and marginalized groups, the lenses through which members of these groups identify and perceive injustice may shape how they act in efforts to

enact change. For example, a dominant group member may engage in social change action either via a process of (a) ingroup collective action, (b) solidarity, or (c) allyship depending on whether the impetus for action spurs from identifying with the affected group itself (e.g., Kunst et al., 2018), from perceived common stigmatization experiences along different forms of inequality (e.g., Cortland et al., 2017), or from perceiving one's ingroup as unjustly privileged (e.g., Leach et al., 2002; Phillips & Lowery, 2020). Future research would benefit from understanding ingroup collective action, solidarity, and allyship as complementary (yet distinct) psychological processes that may lead people to engage in social change to mitigate group-based hierarchy.

5.3. When Do People Seek to Rearrange Group-Based Hierarchies?

Whereas hierarchy maintenance and mitigation have each received ample attention in the political psychology literature, and hierarchy enhancement has received much theoretical (but less empirical) attention, efforts to *reorder* group-based hierarchies have received very limited examination. Thus, it is an intriguing, but relatively open question as to whether marginalized groups may seek to maintain group-based hierarchy, but reorder it such that their group becomes positioned on top. This way in which individuals may seek to influence the hierarchy requires separating some often-conflated elements of group-based hierarchy—specifically, system stability and positional stability. This separation implies that, to the extent that motives underlying hierarchy maintenance action emphasize predictability, stability, and legitimacy (Leach et al., 2002; Jost, 2020), then the current overall system could be maintained even while the position of groups within that hierarchical system are rearranged. For example, individuals may support the idea of a meritocratic system in which rewards should be distributed based on relevant, controllable, individual factors, and individuals can both want to protect this system while rearranging their groups' relative standing within the hierarchy.

When only two groups in a hierarchy are studied at a time (e.g., men vs. women, White Americans vs. Black Americans), then group position and system stability are often confounded in the research design. However, given that actual hierarchies exist in many diverse contexts that include the presence of multiple well-represented groups in society, this diversity implies that the overarching hierarchical system can be maintained while a group's relative position within that system is shifted. For example, Black Americans may seek to shift their group's relative position within the hierarchy, but maintain a hierarchical system in which their racial group dominates over others.

Fitting this perspective, emerging work on SDO suggests that this individual difference orientation may not simply be related to preference for more versus less equality, but rather preference for certain *kinds* of arrangements (Lucas & Kteily, 2018; see also Waldfogel et al., 2021). Whereas those high in SDO generally want to maintain or even exacerbate existing inequalities, this work also finds that some of those *lower* in SDO want to support the advancement of those currently at the bottom of the hierarchy (for example, see Ponce de Leon & Kay, 2021). When given the chance to help if the *dominant* group is harmed, those lower in SDO may decline to do so (e.g., Lee et al., 2011; Lucas & Kteily, 2018).

For example, in an online convenience sample (Study 6, Lucas & Kteily, 2018), the relationships between SDO and empathy differed, depending on if participants were

randomly assigned to consider a student that had qualified for either a school's legacy admission policy that was ending or the school's affirmative action policy that was ending. Specifically, if considering a student who would qualify for a school's affirmative action policy that was ending, SDO predicted less empathy for the marginalized-group student and less opposition to the policy change (Lucas & Kteily, 2018). In contrast, if considering a student who would qualify for a school's legacy admission policy that was ending, SDO predicted *greater* empathy for the dominant-group student and *more* opposition to the policy change.

Overall, this work suggests that rather than only seeking to boost the status of marginalized groups, those lower in SDO are also (albeit, to a weaker extent) supportive of policy changes that are seen as harming a dominant group member. If both types of policies occur (those that boost marginalized groups and reduce advantages of dominant groups), this theoretically could yield rearrangement of the rank order, although more empirical research is needed to make strong claims.

Recent theorizing on triadic social stratification theory (TSST; Caricati, 2018) has considered the position of "intermediate-status" groups—groups positioned between at least two outgroups in a hierarchy. This work suggests that intermediate-status groups could conceivably coalesce with either lower-rank or higher-rank groups to form alliances in pursuit of hierarchy change or hierarchy maintenance, respectively (see Caricati, 2012, 2018; Sollami & Caricati, 2015). Often tested within occupational groups or national group contexts, a central tenet of TSST is that the perceived stability of the hierarchy is an important determinant of the intergroup behavior of intermediate-status group members. For example, across several studies (Studies 1 and 2 of Caricati et al., 2020), Italian participants were provided with information about the hierarchy of several countries: Germany was positioned as the highest status and most powerful, Italy (the ingroup) as intermediate status, and Greece as low-status. Importantly, participants were randomly assigned to read that either the international hierarchy was stable or not (i.e., whether Greece's GDP was increasing or remaining low). Results revealed that participants generally reported greater favorability of an alliance with the alleged high-status group (Germany; Study 1), however, participants' support of an alliance with the lower-status group (Greece; Study 2) was heightened if the hierarchy was positioned as unstable (vs. stable; Caricati et al., 2020). Overall, this work provides intriguing initial evidence that intermediate status groups' coalitional inclinations may differ in strategic ways, depending on their perception of the hierarchy itself (e.g., whether it is perceived as stable) and that some of these inclinations imply hierarchy rearrangement.

Recent work also reveals circumstances in which members of the dominant group anticipate forming a coalition with an intermediate-status group. In this work (Craig & Lee, 2022), the prospect of societal change due to the increasing status and power of Hispanic Americans activated perceptions that both White and Asian Americans will lose social status, which facilitated Whites' perceptions of Asian Americans as a potential ally in maintaining the current racial hierarchy. However, without a catalyst like perceptions of status threat from a growing third group, people's expectations of typical interracial coalitions are quite different. Indeed, among diverse sets of Americans (both White and racial minority group members), the predominate assumption appears to be that specific racial minorities will work together (against the interests of White Americans) for racialized political issues due to perceived interest convergence stemming from racial

stereotypes (Craig et al., 2022). For example, in a racially diverse sample, nine times out of ten, participants reported that Black and Hispanic Americans would coalesce on status-relevant issues such as low-income housing and welfare funding and further that these group's positions would be in opposition to participants' assumptions of Whites' positions on the issues (Craig et al., 2022).

A longitudinal study (Knowles et al., 2022) with a nationally representative sample of White Americans revealed that these types of beliefs about minority collusion may vary based on partisanship. Specifically, compared to White Democrats, White Republicans more strongly endorsed beliefs that minority groups collude and work together and that White people should act as a political bloc to defend their group's interests; these partisan differences occurred at the beginning of the study in 2015 and these beliefs increased over the three-year study duration (Knowles et al., 2022). Despite growing beliefs about minority group collusion among a subset of the White population, it is important to note that members of different marginalized groups do not automatically view one another as prospective coalition partners (see Craig et al., 2012; Craig & Richeson, 2014a, 2016, 2018a; Kaufmann, 2003). Overall, research has just begun to understand the psychological intricacies of coalition-building—both real or assumed—and the conditions in which groups seek hierarchy rearrangement in diverse societies, leaving an exciting avenue for future research to uncover.

6. RESPONSES TO MAINTENANCE OR CHANGE OF GROUP-BASED HIERARCHY

As reviewed above, individuals may interact with group-based hierarchies by working to maintain them, enhance them, mitigate them, or rearrange them. Next, we consider how individuals may, in turn, *react* when the hierarchy is maintained or changes in each of these ways.

6.1. Reactions to Hierarchy Maintenance

Research suggests that several psychological processes work to reduce the extent to which people (and particularly people whose group is dominant in the hierarchy) notice that hierarchy is being maintained (e.g., perceived legitimacy, system justifying ideologies, and legitimizing myths; Jost & Banaji, 1994; Pratto et al., 2006). Predictable differences emerge between the members of dominant and marginalized groups in terms of views of the group-based hierarchy and inequality itself. For example, on average, White Americans tend to perceive that greater progress toward racial equality has been made, compared with the perceptions of members of racial minority groups (although both groups indicated that at least some progress has been made; Eibach & Ehrlinger, 2006; Eibach & Keegan, 2006). Follow-up experiments that manipulated participants' frame of reference for comparison revealed that this group-based difference in perceptions of progress is explained, in part, by the use of different reference points—White Americans compared racial progress against

the poor race relations of the past, whereas racial minority participants compared progress against ideal standards (Eibach & Ehrlinger, 2006).

As another example, an ethnographic field study within a dozen high schools in the US Midwest demonstrated that Black History Month commemorations tended to differ, depending on the student body demographics (Salter & Adams, 2016). In the schools in which the majority of students were White, the Black History Month displays (e.g., posters and imagery) tended to focus on less negative and painful aspects of Black history (e.g., slavery and racism) and more on celebratory and positive aspects of Black history (e.g., famous Black inventors), compared with the displays in schools with majority-minority student bodies. A separate sample of White Americans then rated the different Black History Month displays and these results revealed that on average, White Americans reported more positive affect and liking for the displays derived from majority-White schools (than those from majority-minority schools) and that this preference was strongest among participants who rated their White identity as important to their sense of self (Salter & Adams, 2016).

While the above studies provide evidence of a general tendency toward perceiving increasing progress (particularly among members of the dominant group in the hierarchy), there was no objective measure of racial progress with which to compare participants' ratings to determine if participants were over- or under-estimating the amount of hierarchy. More recent research utilizes a more objective measure to assess tendencies toward viewing the hierarchy as more or less equal than is accurate. That is, recent work (Kraus et al., 2019) has revealed vast underestimates in the average American's estimates of the magnitude of the racial wealth gap. While it is well known that humans tend to be quite poor at making these kinds of estimates (e.g., see Gimpelson & Treisman, 2018; Hauser & Norton, 2017; Phillips et al., 2021), participants' inaccuracies in this work tend to follow a reliable pattern in which the degree of racial hierarchy is consistently underestimated. Specifically, nationally representative samples of Americans were asked to report their perceptions of the wealth of a typical Black, Hispanic, and Asian family on a scale of \$0–\$200, assuming the wealth of a typical White family was \$100 (Kraus et al., 2019). These estimates were then compared against data on racial groups' actual median wealth derived from the US Census Survey of Income and Program Participation. Although it is possible that the respondents have different conceptions than the Census Bureau of what constitutes wealth, the comparison between these numbers suggests that respondents perceived the wealth of Black, Hispanic, and Asian Americans to be much closer to White Americans' wealth than may be accurate (89.3% of respondents overestimated equality by 20 or more percentage points and 61.5% overestimated equality by 50 or more percentage points).

Providing further empirical evidence to this point, recent work suggests that even if presented with information about persisting racial disparities in economic outcomes (highlighting an ongoing hierarchical system), people update their perceptions of past (1963), but not current (2016) wealth gaps, in a way that maintains perceptions of the current status quo as more equal than is accurate (Onyeador et al., 2021). Specifically, rather than adjusting their overestimates of contemporary racial economic equality, individuals who read information about economic disparities reported that the past was more equitable, compared with those who read about a topic unrelated to race (left-handedness). This finding suggests that one way people may make sense of ongoing racial disparities and maintain one's view of society as fair and progressing is to view the past as not so bad.

The predictable tendencies and misperceptions outlined above may be one example of a broader “myth of racial progress” narrative (Richeson, 2020). Social dominance theory may consider this type of narrative an example of hierarchy-enhancing legitimizing myths—cultural ideologies widely known within a society that serve to maintain or enhance group-based inequality and hierarchy—as perceiving society to invariably move towards justice without outside intervention could legitimize the status quo and serve to stifle support for social change (why act, if things will always get better?).

This work adds to an emerging research area focused on understanding dominant group reactions to evidence of group inequity (i.e., unfair group hierarchies; Knowles et al., 2014; Phillips & Lowery, 2018). Some research has considered the invisibility hypothesis, or the idea that dominant groups, in particular, are less likely to notice advantages and unfairness that benefit them (e.g., McIntosh, 1989; Pratto & Stewart, 2012). For instance, it is possible that such social advantages are inherently less visible than are social disadvantages (Davidai & Gilovich, 2016; Phillips & Jun, 2022; Sawaoka et al., 2015; Wu & Dunning, 2020), due to cognitive mechanisms that prioritize potential threats and loss. However, other work has emphasized motivated factors at play, including basic needs for self-esteem, group-esteem, and preference for meritocracy (Knowles & Lowery, 2012; Knowles et al., 2014; Phillips & Lowery, 2015, 2020; Lowery et al., 2007).

Motivation may also play a role in shaping attention itself: for instance, those higher in SDO (Waldfoegel et al., 2021; see also Kteily et al., 2017) or higher in social class (Dietze & Knowles, 2016; Kraus et al., 2010; see also Magee & Smith, 2013) are less likely to attend to inequality, in part due to an emphasis on their own instrumental goals. Attempting to integrate these perspectives, Phillips and Lowery (2018) propose “herd invisibility,” in which both the cognitive and motivational factors that lead individual dominant group members to deny the existence of inequality in turn shape *social constructions* of inequality, which may minimize perceptions of unfair advantages (see also, Jun et al., 2022). Overall, this research suggests that the ongoing maintenance of the hierarchy may be contributed to, in part, by general tendencies of “not seeing” inequality or perceiving an inexorable trend toward social progress.

6.2. Reactions to Hierarchy Enhancement

To our knowledge, little research within psychology has considered reactions to the *enhancement* of group-based hierarchies (but see Eibach & Keegan, 2006). However, given that hierarchies can and regularly do become more extreme (e.g., Alvaredo et al., 2013; Gates, 2020), this represents an area that will likely benefit from future work. Here, we briefly consider related phenomena: how people react to hierarchy enhancement in small team contexts and how people understand growing economic inequality.

In smaller team contexts, individuals tend to react more strongly to the experience of status loss than to status gain (Pettit et al., 2010; Pettit & Lount, 2010; Neely & Dumas, 2016). For instance, when faced with a growing hierarchy, people are more willing to cheat to avoid falling behind than they are to cheat to get ahead (Pettit et al., 2016). This fits with prospect theory perspectives, which suggest that humans are generally more sensitive to losses than to gains. In turn, this work suggests that when group-hierarchy is enhanced, people ought to react in part based on their own group position: if their position is reduced (even

symbolically), reactions ought to be more negative, as compared to the degree of positivity when their position is improved.

In societal-level economic contexts, people tend to be motivated toward increased collective action and support more redistribution when they perceive rising inequality (Cruces et al., 2013; Kuziemko et al., 2015). However, both cognitive and motivational forces often prevent people from perceiving the existence of exacerbated inequality (Hauser & Norton, 2017; Phillips et al., 2021). This work shows that beliefs about one's ability to climb the hierarchy (e.g., beliefs in meritocracy) can lead members of marginalized groups to justify existing inequality more and perceive less discrimination and social inequality (McCoy & Major, 2007; see also Davidai & Gilovich, 2015). Those who are slipping behind may not always notice this change, but when they do, they ought to be especially driven to act. In both cases, perceptions of mobility may also mitigate reactions to hierarchy enhancement, such that growing inequality is more tolerated to the extent individual mobility is still perceived to be possible (Day & Fiske, 2017).

6.3. Reactions to Hierarchy Mitigation

What happens when people perceive others actively engaging to attempt to mitigate an existing hierarchy (e.g., individuals engaging in collective action)? Recent work suggests that it may depend on the form of action being enacted. For example, dominant group members—particularly, those generally resistant to social change (more so than those open to social change)—are more likely to support making concessions to enact social change, if those collectively acting engage in non-normative nonviolent action (e.g., civil disobedience; Shuman et al., 2021). Fewer concessions were supported if individuals engaged in normative nonviolent action (e.g., peaceful demonstrations) or violent action (e.g., riots), or did not act at all. The authors suggest that this tactic is particularly effective because non-normative nonviolent action reflects the best balance of disruption and perceived constructive intentions (i.e., constructive disruption; Shuman et al., 2021). That is, those engaging in non-normative nonviolent action are perceived to have positive intentions while still being disruptive enough to draw attention with the non-normativity of the action.

In addition to understanding how people respond to those collectively acting, a growing body of work suggests that people are quite sensitive to potential threats to the hierarchy and their status within it. For example, work examining responses to social progress highlights that making salient the progress that marginalized groups have made can lead to backlash among certain segments of the dominant group (e.g., Wilkins & Kaiser, 2014; Wilkins et al., 2017). Specifically, this work finds that among members of dominant groups (e.g., White Americans, men) who hold more status legitimizing beliefs, information that marginalized groups are making social gains (e.g., racial minorities, women) tends to lead to greater perceptions that their own dominant group is discriminated against (see Wilkins & Kaiser, 2014; Wilkins et al., 2017, 2018).

Furthermore, recent research suggests that people view population shifts within social hierarchies as potentially threatening to their ingroup's status, if one's ingroup is not alleged to be the one growing in size (for recent reviews, see Craig et al., 2018a, 2018b). This research is consistent with classic theorizing on group threat theory, which highlights the links between concerns about one's position in the hierarchy and intergroup attitudes

(“group threat theory,” Blalock, 1967; Blumer, 1958). Specifically, this perspective (Blumer, 1958) posits that prejudice toward minority groups stems from majority group members’ feelings of concern regarding their dominant position, a proposition that is consistent with other work suggesting that anti-immigrant attitudes are a result of concerns about one’s economic interests (Bobo, 1999). Blalock (1967) further considered group position concerns and linked it to prejudice—particularly, suggesting that perceptions of group size often serve as a proxy for perceived group power and that larger minority groups are seen as economic and political threats to members of the dominant group. This work is consistent with classic political science work (Key, 1949) in which White southern politics were driven by an effort to maintain White rule in so-called Black belts (areas with large proportions of Black residents). Particularly, this perspective suggested that Whites living in areas with larger percentages of Black residents maintained one-party (Democratic) rule to (1) prevent partisan competition for Black people’s vote and (2) unify to strengthen opposition to any federal attempts to interfere in racial policy.

A growing body of social scientific research (Burrow et al., 2014; Craig & Richeson, 2014b, 2014d, 2017, 2018a, 2018b; Danbold & Huo, 2015; Major et al., 2018; Outten et al., 2012; Skinner & Cheadle, 2016; Willer et al., 2016) considers how demographic changes toward increasing racial diversity tend to be viewed as a potential evidence of hierarchy mitigation (and possibly rearrangement; for recent reviews, see Craig et al., 2018a, 2018b). This work typically experimentally manipulates the content of news articles and reveals that making salient the increasingly diverse national racial demographics elicits a host of intergroup and ideological outcomes among members of the current majority group (i.e., non-Hispanic White Americans). For example, presenting information about the changing national racial demographics (vs. control information) leads White Americans to express greater anxiety (Burrow et al., 2014), more anger and fear toward minority groups (Outten et al., 2012), and more explicit and automatically activated racial bias (Craig & Richeson, 2014b; Skinner & Cheadle, 2016), as well as endorse assimilation more strongly (Danbold & Huo, 2015), endorse conservative policy positions and political groups more strongly (Craig & Richeson, 2014d, Willer et al., 2016), and express greater concerns about facing anti-White discrimination (Craig & Richeson, 2017, 2018b). Indeed, in this work, presenting White Americans with information about trends toward greater racial diversity in the United States elicits greater perceptions that White Americans will face discrimination (particularly, in the future; Craig & Richeson, 2017), and one study finds that this also elicits support for policies that would require employers to make special training programs for White workers and to make special efforts to recruit White workers (Craig & Richeson, 2018b). Such policies, if prophylactically enacted, could serve to enhance the existing racial hierarchy.

This body of research implicates concerns about Whites’ diminished societal status (in terms of group status, access to resources, and cultural prominence) as driving forces underlying these effects (see Craig & Richeson, 2014b, 2014d, 2017; Danbold & Huo, 2015; Major et al., 2018; Outten et al., 2012). Group status threat is often assessed in the literature as concern for the ingroup’s status and influence in society and is often assessed relatively (e.g., perceptions that White Americans will have more or less status and influence than minority groups). There is also work identifying prototypicality threat (concern that one’s group will no longer be seen as the cultural prototype, e.g., Danbold & Huo, 2015, 2021), symbolic threat (concern for unmarked benefits related to belonging; Stephan et al., 2009), and realistic threat (concern for group access to resources; Stephan et al., 2009).

Additionally, research suggests that existential concerns that one's racial group is disappearing may also be activated by salient information about White population decline (e.g., Bai & Federico, 2020). That is, information about the ingroup declining in population can elicit existential threat: concern for the continuing existence of one's group (Bai & Federico, 2020; Wohl et al., 2020). Overall, this work reveals that anticipating increasing diversity can activate a number of different forms of intergroup threat (e.g., group status, realistic, symbolic, existential) and is frequently examined among White Americans.

6.4. Reactions to Hierarchy Rearrangement

The prospect of a rearranged hierarchy is likely threatening among groups not portrayed as gaining in status or power in this prospective new hierarchy. Considering that the hierarchy might be rearranged could also elicit concerns regarding system stability and predictability. For members of the dominant group, hierarchy rearrangement implies loss of relative status, at minimum, and even the potential for hierarchy inversion. For example, White Americans' perceptions of how minorities will use power, if gained, greatly shifts their openness to relinquish group dominance (Kteily et al., 2021). Recent work on this idea suggests that some White Americans perceive that Black Americans would use any gains they make in power to dominate other groups and these perceptions uniquely predict opposition to policies that would empower Black Americans (e.g., affirmative action) as well as predict support for efforts that would maintain a hierarchy in which Whites are dominant (Kteily et al., 2021). As noted earlier, in a large, nationally representative panel of White Americans, Republicans and Independents showed increasing belief over time that minorities are working together against Whites' interests ("minority collusion"). Such perceptions predict support for the alt-right movement and opposition to Black Lives Matter (Knowles et al., 2022). Overall, the extent to which dominant group members assume that marginalized groups want to rearrange the hierarchy and are even colluding to do so predicts threat and efforts to stymie this perceived rearrangement. This implies that if a rearrangement actually occurred, dominant group members would perceive shifts in status and power that would trigger all of the threats discussed in the hierarchy mitigation section.

One's position in the hierarchy can also shape the degree to which rearrangement is perceived as threatening. Specifically, work on last-place aversion (Kuziemko et al., 2014) finds that people in the penultimate position are particularly sensitive to the possibility of moving to last place in a hierarchy. For example, people who were randomly assigned to second-to-last place were more likely to give money to the person one rank above rather than the person one rank below (Kuziemko et al., 2014). Taken to a policy level, last-place aversion suggests that low-income individuals might oppose redistribution because it could differentially help the group just beneath them and has been used to explain why individuals making just above the minimum wage are the most likely to oppose its increase (Kuziemko et al., 2014).

Relevant to this idea, one paper has examined how other racial minority groups (e.g., Black Americans and Asian Americans) react to information about demographic change that is driven by another minority group (i.e., Hispanic population growth). Given that Hispanic growth represents the growth of an outgroup to non-Hispanic Black or Asian Americans, one may expect that such information would also elicit threat reactions, similar to what has been observed among White Americans. Indeed, consistent with this possibility,

Black and Asian American participants who read an article highlighting Hispanic population growth (vs. control information) reported greater preference for conservative positions (or less support for liberal positions) on a variety of political issues (Craig & Richeson, 2018a). Taken together with the prior work on White Americans' reactions to racial shifts, this body of work suggests that anticipating demographic change and potential for hierarchy rearrangement can elicit threat responses and support for policies that would maintain the status quo among groups not portrayed as driving the population growth.

7. OPPORTUNITIES FOR FUTURE RESEARCH

Ample previous research has tried to answer the question of why group-based hierarchies exist and are sustained. Still more work has also considered the circumstances in which people seek to reduce hierarchy via increasing marginalized groups' rank in the hierarchy. Nevertheless, a number of unanswered questions call for future research. We summarize these below.

7.1. Understudied Interactions with Group-Based Hierarchy

As our review above reveals, research has just begun to consider when groups may seek to rearrange (rather than reduce) the hierarchy and what other groups' responses are to the prospect of hierarchy inversion (Kteily et al., 2021). Some of the prior work examining when people seek to engage in political action to improve the position of marginalized groups or how dominant groups respond to hierarchy threats may actually be tapping into these hierarchy-rearrangement concerns, but most studies do not use methods that allow for this to be distinguished from hierarchy-mitigation concerns. Relatedly, almost no empirical psychological research considers hierarchy enhancement or exacerbation—when groups may seek to make the hierarchy steeper. Whereas hierarchy maintenance and mitigation efforts have received much empirical attention, groups may attempt to manage hierarchy in other ways. Future work should explore these possibilities.

Another area in need of further clarification is when and why evidence of inequality and hierarchy is, at times, accepted and when it is misperceived (see McCall et al., 2017; Hauser & Norton, 2017; Phillips et al., 2021). For example, while evidence of inequality and existing hierarchies can spur people towards hierarchy-mitigating policy support and social action (e.g., Dietze & Craig, 2021; McCall et al., 2017), such evidence can also lead to psychological processes that serve to maintain the legitimacy of hierarchy, thus, thwarting the likelihood of engaging in reparative action (e.g., Onyeador et al., 2021). Understanding which process is likely to occur in response to evidence of inequality is essential for predicting political behavior.

7.2. Unpacking “Threat”

An area for future clarification is in explaining how to predict which *types* of threats are elicited by expected challenges to the hierarchy. Theoretical traditions often vary in their focus on different forms of threat. For example, Blalock (1967) delineates two forms

of threat: (a) economic (e.g., concerns about loss of jobs), and (b) political threat (e.g., concerns about losing political control and power). One could also distinguish (Kinder & Sears, 1981; Sears & Kinder, 1985; Stephan et al. 2009) between realistic threats (threats to the physical welfare or resources of the ingroup, see also “realistic group conflict theory”; Sherif et al., 1961; Campbell, 1965; LeVine & Campbell, 1972) and symbolic threats (threats to the ingroup’s system of meaning and values; see also Henry & Sears, 2002; Kinder & Sanders 1996; Meertens & Pettigrew 1997; Sears & Henry 2003).

Yet many times it is not obvious which forms of threat may be elicited in different forms of hierarchy-challenging contexts. For example, while group status threat (i.e., concerns that one’s group will lose status) has been found to account for why information about changing demographics influences policy preferences (Craig & Richeson, 2014d), reducing concerns about Whites’ racial status *did not* reduce concerns about facing anti-White discrimination following the same article prime (Craig & Richeson, 2017). Instead, assuaging concerns about no longer being the cultural prototype alleviated Whites’ perceptions that anti-White discrimination will rise in a racially diverse future United States (Craig & Richeson, 2017). Thus, our understanding of which different forms of intergroup threat (e.g., group status, realistic, symbolic, existential) are elicited and drive different outcomes following information that the hierarchy may be changed is currently incomplete.

An additional consideration in need of further attention is that threats can be experienced at the group level (e.g., group-esteem threat; Branscombe et al., 1999; group-dominance threat; Chow et al., 2013; fraternalistic relative deprivation; Runciman, 1966) or at the personal level (e.g., threats to one’s personal sense of self-esteem or morality; Phillips & Lowery, 2020; Brown & Craig, 2020; inequity in interpersonal relationships; Adams, 1965). Perceptions that one is threatened at the group level and the personal level may, at times, coincide, but this is not always the case. For example, past work suggests that changing demographics information leads Whites to report that they are personally-anxious (Burrow et al., 2014) as well as to report that the status of White people (as a group) is under threat (e.g., Outten et al., 2012). In contrast, information about group privileges (e.g., Phillips & Lowery, 2015; see also Wright et al., 1990) can lead dominant group members to agree that their group is privileged, while still disagreeing with the idea that they are *personally* privileged. In attempts to prove this point, dominant group members even work harder to bolster the view of oneself as not personally privileged (Phillips & Lowery, 2020). Taken together, the sheer variety of different forms of group-relevant threats and the lack of clarity in the circumstances under which one will experience different forms of threat will likely hamper any intervention efforts and thus, is in need of further research.

7.3. Complex Hierarchies: Multiple Groups and Individuals

With notable exceptions (e.g., Benjamin, 2017; Collingwood, 2020; Cikara, 2020; Craig & Lee, 2022; Dixon et al., 2020) and despite more complex theorizing (e.g., Sidanius & Pratto, 1999), much empirical research focuses on dynamics between two groups at a time, even within diverse hierarchies, which limits our understanding of how groups relate to one another and to hierarchical systems in diverse societies. When do people reach out to members of other groups to either change or maintain the hierarchy? How do intermediate-ranked groups interact with the hierarchy and how do marginalized and dominant groups

respond towards intermediate-status groups? Social scientific research is just beginning to understand these complex dynamics, but such work is essential for a more complete understanding of politics in diverse societies.

Another tension in the current literature regards who exactly is being theorized about when group behavior is evoked: elites or citizens? For example, some theories especially emphasize the elite and powerful members within a dominant group (e.g., interest convergence theory, Bell, 1980; see also Acemoglu & Robinson, 2006; Chow et al., 2013; Jun et al., 2017). The norms and socialization processes set by these powerful group members may in turn shape the experience of the masses. From this perspective, altruism or genuine intergroup helping motivations become less feasible and proclamations of such motivations will elicit suspicion (Konrath et al., 2016; Kristofferson et al., 2014).

Other work theorizing about group behavior may instead emphasize average citizens, including those who may deviate from the group norm. This focus on individual group members, rather than the group as a whole (i.e., as led by elites), presents new potential motives: alternate sources of esteem (e.g., moral or political identities; Brown & Craig, 2020; Phillips & Lowery, 2020) or the desire for justice (Lowery et al., 2009). From this view, genuine allyship from dominant group members appears more feasible. Indeed, individual-esteem and justice motives, including egalitarianism and fairness, are also powerful in guiding action. These may represent an opening in which the dominant position of advantaged group members becomes psychologically untenable (“poisoning the consciences of the fortunate,” Leach et al., 2002), leading people to give up group material interests to satisfy alternate motives. It is possible that genuine coalitional action across social groups primarily endures as long as a sense of shared interest occurs (e.g., Cortland et al., 2017). The burgeoning research examining underlying motives of dominant group allies (e.g., Selvanathan et al., 2020; Radke et al., 2020) will help elucidate this puzzle, but further research comparing motives of both citizens and elites is warranted.

8. CONCLUSION

This chapter provides an overview of group-based hierarchy, including theories about what creates and sustains hierarchy, how individuals may interact with group-based hierarchy—acting to maintain it or change it—as well how people react when the hierarchy is maintained or in flux. Some ways in which people take action to influence an existing group-based hierarchy were well-examined within the literature (e.g., when people may seek to maintain the existing hierarchy or mitigate it), whereas other forms of interaction have more nascent empirical evidence (e.g., conditions in which people seek hierarchy enhancement or rearrangement). Then, discussing the literature on how people respond when the hierarchy is in these different states, we again found that some research areas were well trodden (e.g., how people respond to the notion that group-based hierarchy may be mitigated), while others are still developing (e.g., how people respond when hierarchy is exacerbated). We identified how certain forms of interaction with the hierarchy have been empirically conflated (e.g., distinguishing hierarchy-enhancement from hierarchy-maintenance and hierarchy-mitigation from rearrangement). We ended by considering several areas that currently lack clarity, which we believe present opportunities for

valuable future contributions. These open questions and more await further investigation into how people exist within and interact with group-based hierarchical systems. In an unprecedented time of social engagement, sociocultural change, and contact (e.g., increasing diversity and globalization), understanding how individuals experience and respond to hierarchy is imperative.

CHAPTER 24

POLITICAL IDENTITIES

LILLIANA MASON

THE very nature of political identities—in particular partisan and ideological identities—sits uncomfortably with normative ideals of democratic behavior. Though politics has long been understood as rooted in identity-motivated behavior (i.e., Campbell et al. 1960), these motivations do not necessarily match an idealistic view of voters as rational, objective, and informed (Achen and Bartels 2016). Nonetheless, social identification with political groups is a crucial element driving political behavior and must inform any study of citizens' participation, organization, and judgment. The field of political psychology allows us to combine long-studied theories of partisan identity with social-psychological literature that explains social identity and intergroup conflict. By using psychological theories to understand political identities, recent research has been able to explain how voters process information, take political action, respond emotionally, and even exhibit prejudice against their political opponents. While these behaviors are often not “rational” from an individual economic perspective, they are certainly in line with perfectly normal and predictable psychological motivations (Huddy 2018).

The study of identity in political science has changed across time. The “Michigan School” approach made it clear that social identities influenced political behavior, and that partisanship itself could be thought of as a social identity, capable of skewing partisans' understanding of the political world (Campbell et al. 1960). This view was challenged in later decades, as a more instrumental view of partisanship took hold (i.e., Fiorina 1981). The instrumental argument suggested that voters made rational political choices, based on an objective observation of political events and figures, and in their individual economic interest. The biasing effects of partisan identities were re-examined in the early 2000s (i.e., Bartels 2002), leading to a new body of research that took advantage of social identity theory and other psychological theories to better inform political science's understanding of the role of identity in politics. In particular, more recent research considers partisan and ideological identities as social identities, distinct from a policy-oriented understanding of these concepts (i.e., Huddy, Mason, and Aarøe 2015; Ellis and Stimson 2009). By examining the “issue-based” and “identity-based” elements of partisanship and ideology separately, this work allows researchers to be more precise in our measurement of and predictions about political behavior.

Recent research has also begun to examine the way that partisan identities operate alongside other important social identities (Mason 2018b). Indeed, an alignment between political and other social identities such as race, religion, and even “place” can provide additional energy to political or partisan conflicts (Cramer 2016; Jacobs and Munis 2019; Margolis 2018; Tesler and Sears 2010a; M. Levendusky 2009). The increasing alignment between social identities, or “social sorting,” can be used to explain another identity-based political phenomenon—what is generally known as “affective polarization” (Iyengar, Sood, and Lelkes 2012). This refers to a view of polarization that centers on how partisans feel about each other rather than what they believe government should do. The process of social sorting has been documented in American politics, and its effects are also documented in international contexts, under the terminology of “cleavage structures” (Selway 2011b). By thinking of polarization in an identity-based manner, political psychology has been able to better inform scholarship on political polarization—improving measurement and operationalization of the concept.

Through understanding the identity-based motivations underlying political behavior, it becomes easier to explain seemingly irrational behavior of voters, emotional responses to political events, increasing polarization, and the confluence of prejudice and partisanship.

Politics is essentially formalized intergroup conflict. Without a firm understanding of the group dynamics underlying political behavior, it is difficult to fully understand politics as a whole. In the interest of space, this chapter will mainly examine social identities as they are related to partisanship and ideology. Other chapters will directly address additional social identities and their direct relationships with political behavior and politics (see Perez and Vicuna, Chapter 25, this volume; Huddy, Chapter 21, this volume).

1. MAJOR THEORETICAL APPROACHES TO IDENTITY FORMATION

To understand the formation and activation of political identities, we must first understand how individuals form groups in the first place, and what those group attachments mean for behavior and judgment. Individuals can be organized into groups in multiple ways, for multiple reasons, and can feel attached to these groups to differing degrees. I focus here on four major approaches to the study of social group formation. Each of these can provide a different perspective on the underlying dynamics and psychological motivations for social group or identity formation and functioning.

1.1. Evolutionary Perspective

At face value, an evolutionary perspective on group formation is quite simple to conceptualize. Humans have always formed social groups in order to survive and reproduce (Petersen, Chapter 7, this volume). Families, communities, even civilizations would be impossible to imagine without a natural human inclination to unite with other individuals in pursuit of cooperation and group preservation. Caporael and Baron (1997) write that social

groups are “the mind’s natural environment” (pg. 317). We can see and experience that human psychology is deeply rooted in social relationships. Van Bavel and Pereira (2018) note that social groups (like political parties) fulfill basic social needs, like “belonging, distinctiveness, epistemic closure, access to power and resources, and provide a framework for the endorsement of (moral) values” (pg. 5).

From this perspective, basic activities such as childrearing, food gathering, tool development, food production, and group defense are all reliant upon a social group working together. Human survival requires cooperation between group members, trust in the loyalty of other group members, defense of the group from outsiders, and the reliability and enforcement of group norms. All of these requirements can be observed in modern political intergroup relations.

Cikara, Botvinick, and Fiske (2011) even identify group-formation patterns in neural activity, suggesting a deep human inclination toward identifying, forming, and maintaining group boundaries. These are generally most identifiable in the case of ingroup formation—not outgroup derogation (a finding consistent with Marilynn Brewer’s 1999 findings).

In particular, McDermott and Hatemi (2018) consider the use of an evolutionary perspective essential to understanding contemporary populist and identity-based politics. They argue that the basic human needs for group cohesion across time have typically devolved to concerns over “resource allocation, in-group defense and out-group discrimination, and attempt to regulate sex and reproduction” (pg. 2). They find clear parallels between these types of long-standing group-based motivations in contemporary political conflicts over “access to health care, the status of transgender individuals and a woman’s right to choose, how to view out-groups such as immigrants, and how we defend ourselves in the war against terrorism” (pg. 2). These may be contemporary examples of political debates, but they can be seen as enduring examples of deeply-rooted human needs for status, security, and resources.

1.2. Categorization and Group Salience

Self-categorization theory (SCT) attributes group cohesion to cognitive factors such as the situational salience of group identity. In this perspective, individuals hold multiple concepts of self, and the function of the social self is situation-specific. A person will consider themselves to be part of a social group if the situational context brings the group to mind. A particular group identity often becomes salient in the clear presence or reminder of a relevant outgroup. As the contrast between the two groups grows more prominent, a person “depersonalizes” their own individual view of themselves, and feels more similar to other members of the group they belong to (Turner et al. 1987). The shift from personal to collective identity is accompanied by increased adherence to group norms and heightened self-stereotyping, factors that can lead to political cohesion and cooperation (Turner et al. 1987; Terry and Hogg 1996).

Much of this process of depersonalization relies on a strong ingroup “prototype.” The prototype can take the form of a leader whose ideas and suggestions group members comply with. This compliance confers status onto the leader, creating a status-based differentiation between leaders and followers (Hogg 2001). Alternately, group members may generate a group prototype by examining the social makeup of the group. Egan (2020) finds that some

partisans will alter their professed ethnic and religious identities to conform with the party's social prototype.

1.3. Realistic Group Interest

Realistic group interest theories focus on the role of perceived or real inequalities between groups as drivers of group-based behavior. These theories include realistic group conflict, relative deprivation, social dominance theory, and Blumer's theory of group position (Blumer 1958; Kteily, Sidanius, and Levin 2011; Sidanius et al. 2007; Bobo and Hutchings 1996). Together, these theories suggest that group membership is politically important to the extent that tangible group gains and losses drive group members' political decisions.

According to *realistic group conflict theory*, group members are motivated to take action and stereotype outgroup members when two or more groups are competing over limited resources (Sherif and Sherif 1953). *Relative deprivation theory* predicts political participation and angry and resentful emotions as a result of the judgment that one's group is unfairly disadvantaged in relation to another group (H. J. Smith and Pettigrew 2015). *Social dominance theory* predicts political behavior rooted in a "preference for inequality among social groups" (Pratto et al. 1994). In particular, it predicts opposition to political policies that reduce inequality. Finally, *Blumer's theory of group position* locates the source of racial group prejudice in the importance of the dominant racial group's superiority over the subordinate racial group. Blumer writes, "the dominant group is not concerned with the subordinate group as such but it is deeply concerned with its position vis-a-vis the subordinate group" (Blumer 1958, pg. 4). In general, these theories are concerned with which groups get power and which have the most power (see Craig and Phillips, Chapter 23, this volume).

Group interests are generally more effective than individual self-interest at motivating political behavior—although the two can often be intertwined (Bobo 1983). In the case that they are conflicting, however, we can observe seemingly "irrational" political behavior, in which individuals ignore their self-interest in pursuit of group interests. For example, racial group interests motivated some uninsured white Americans to oppose the 2010 Affordable Care Act, which would have provided them with health insurance, but would have also provided care to Black Americans and offered a political victory to the first Black American president (Tesler 2012). In fact, much of the work on the topic of realistic group interest is rooted in racial intergroup conflict.

1.4. Social Identity Theory

Social identity theory (SIT) is a precursor to self-categorization theory described above. The main difference between the theories is that SCT is mainly cognitive in nature, while SIT includes other motivations linked to the protection of group status and esteem (Tajfel and Turner 1979). The earliest versions of social identity theory developed by Tajfel (1981) and Tajfel and Turner (1979) placed key emphasis on the need among group members "to differentiate their own groups positively from others to achieve a positive social identity" (Turner et al. 1987, pg. 42). Social identity theory was originally demonstrated via "minimal group paradigm" experiments, in which relatively meaningless group labels were

randomly assigned to experimental subjects who nonetheless proceeded to privilege their own assigned group over the other (for a summary, see Brewer 1979). Some subjects were willing to accept a loss for their own group as long as the outgroup lost even more (Billig and Tajfel 1973). This theory helps to explain why group members might forego the “greater good” for all groups in order to achieve higher status for their own group.

Social identity theory is primarily related to positive feelings about one’s ingroup, and only secondarily related to negative or derogatory feelings about a relevant outgroup (Brewer 1999). According to this theory, outgroup hatred or prejudice arises only when a group’s status is threatened by an outgroup.

Social identities can also vary in the strength of a person’s attachment to the group, and that strength of attachment can alter reactions to status threats. Those who are strongly attached to a group are more likely to respond to group status threats with anger—according to a related theory known as *intergroup emotions theory* (Mackie, Devos, and Smith 2000; E. R. Smith and Mackie 2015; Eliot R. Smith, Seger, and Mackie 2007). This theory combines social identity theory with *appraisal theory* (Brader and Gadarian, Chapter 6, this volume) to demonstrate that when a group member is strongly attached to the group and can identify the source of the status threat, they are likely to respond to the threat with anger—an emotion that generally encourages action. If a group member is either weakly attached to the group or does not know the source of the status threat, they are more likely to respond with anxiety—an emotion that is related to avoidance (Brader and Gadarian, Chapter 6, this volume). Importantly, this theory argues that individual group members can feel emotions on behalf of the group—unrelated to their own individual circumstances.

Another theory that emerges from SIT is *uncertainty-identity theory* (i.e., Hogg 2000, 2014; Hogg et al. 2007). This theory identifies uncertainty about oneself as a motivator for forming group identities. Self-uncertainty can emerge from widespread social conditions such as war or disaster—or it can emerge from individual conditions such as unemployment or divorce. Groups provide distinctive attributes that group members can use to prescribe their own attitudes, feelings, and behavior—providing individuals with a sense of who they are and what they should think and do. Under conditions of extreme uncertainty, individuals may be motivated to join extremist groups—whose rigid structure of strict boundaries and uniform beliefs and behaviors can provide relief from extreme or enduring uncertainty.

2. PARTISANSHIP AND IDEOLOGY: ISSUES AND IDENTITIES

With this understanding of how identities form and how they can affect behavior, I move to the topics of partisanship and ideology. The theories of social identity and group cohesion are crucial for informing a complete understanding of the role of partisanship and ideology—two concepts that have not always been understood as identities.

2.1. Traditional Views of Partisanship and Ideology

Early studies of American political behavior cited partisan identity as a central predictor of vote choice (Campbell et al. 1960; Berelson 1962; Lazarsfeld 1944). Campbell et al. (1960)

considered partisanship to be a “perceptual screen” through which voters perceived politics and political figures in a way that was more generous to their own party than to their outparty. This view—often referred to as the “Michigan School” approach—was consistent with many of the theories of group identity discussed above. Partisanship was considered to be a group identity, and also to be informed by other group identities. Campbell et al. (1960) noted that racial, religious, and other identities could influence which party a person voted for. But further, partisanship itself operated like an identity—it was learned during childhood from parents and friends and continued to be enforced by social environments and contexts throughout adulthood. A person’s vote was only partially motivated by their preferred policies. It was also an act of group-based solidarity and a decision that did not require much deliberation for partisans.

Over the next twenty years, views on partisanship evolved, with Fiorina (1981) writing that, instead of an identity, partisanship was more like a reasoned decision that voters made based on a “running tally” of their evaluations of a party and its leaders. In this view, voters were choosing candidates because they believed the candidate and their party was more in line with the voter’s own preferences for governing. This was consistent with the rational choice perspective of Downs (1957). Rather than being about identity, voting in this theory was related to assessments of issues and policies. Normatively, this approach was reassuring. Voters that make decisions based on impartial thought and evaluations are participating in democracy in a reasonable and responsible manner.

Another 20 years later, though, American political science returned to the idea of partisanship as a biasing factor in partisans’ understanding and evaluation of politics. Bartels (2002) urged political scientists to go “Beyond the Running Tally,” revealing evidence that partisans were, in fact, biased toward their own party in their assessments of political reality. Their evaluations of the American economy, policy beliefs, presidential traits, performance, approval, and factual questions about the level of unemployment or inflation were consistently related to partisanship. This study was one of many that pushed the study of American political behavior back toward an identity-focused view of partisanship, where it stands now.

Similarly, ideology has traditionally been understood as a somewhat rational coherent set of policy preferences or values—a “system of beliefs” (Converse 1964). But in more recent research, the labels “liberal” and “conservative” have come to be understood as both a description of policy attitudes and a group label—two concepts that are not always perfectly correlated (Ellis and Stimson 2009).

Overall, the extent to which partisanship and ideology behave like a social identity or like an issue-based decision likely depends on the political context—including the positions and behavior of the two parties as well as the degree of partisan polarization. Here, I present evidence supporting the identity-based nature of partisanship and ideology. Social identities can warp political evaluation and decision-making, and are therefore an important phenomenon central to the normative underpinnings of democracy (Achen and Bartels 2016).

2.2. Measuring Partisanship and Ideology as Social Identities

2.2.1. *American Partisanship*

Green, Palmquist, and Schickler (2004) and Greene (2004) reintroduced the concept of American partisanship as a social identity in the early 2000s. Green et al (2004) explicitly

rejected the construct of social identity theory, but nonetheless likened partisanship to a religion (see also Finkel et al. 2020). Greene (2004, 2002) explicitly argued for a measure of partisanship rooted firmly in social identity theory—using the 10-item *Identification with a Psychological Group* (IDPG) scale (Mael and Tetrick 1992). He found this identity-based scale to be a better predictor of partisan attitudes and behavior than the traditional 7-point scale of partisanship commonly used by the American National Election Studies. Huddy, Mason, and Aarøe (2015) also found that a reduced, 4-item version of the IDPG scale was a more powerful predictor of partisan anger, enthusiasm, and activism than either the traditional 7-point scale or a measure of issue extremity. Partisan identity could even be detected on an implicit level, with partisans responding to party cues faster than they can cognitively process them Theodoridis (2017). According to these empirical metrics, partisanship does function as a social identity for many Americans—with the ingroup preference and biased political judgment that implies.

2.2.2. *American Ideology*

Although the traditional (and common) understanding of ideology is directly related to political issues and values, recent scholarship has begun to examine the potential for an identity-based element of ideology—considering the groups “liberals” and “conservatives” as social entities theoretically independent of policy attitudes. Ellis and Stimson (2009, 2012) identified a difference between what they termed “symbolic” and “operational” ideology. Symbolic ideology acts more like an identity, while operational ideology is related to policy attitudes. They identified a large number of “symbolic” conservatives who were “operationally” liberal (“conflicted conservatives”). In other words, many self-identified conservatives held generally liberal policy attitudes. The same was not the case among self-identified liberals, whose symbolic and operational ideology was more consistent.

Claassen, Tucker, and Smith (2014), however, were able to identify conflicted liberals as well, finding that around 30% of Americans are conflicted conservatives and 20% are conflicted liberals. Importantly, conflicted conservatism is related to Republican and conservative identities, low political knowledge, religiosity, and Fox News exposure. Conflicted liberalism is related to Democratic and liberal identities, low political knowledge, and Black or Hispanic ethnic identities.

Further research explicitly measured ideology as a social identity, using items similar to the partisan social identity measure—assessing individuals’ social attachment to their ideological group labels (Malka and Lelkes 2010; Mason 2018a; Devine 2015). This work demonstrated that many self-identified liberals and conservatives do consider themselves to be socially attached to other people who share their ideological group label, and that the strength of this identity affected their feelings toward and evaluations of their ideological outgroup, independently of their policy preferences.

2.2.3. *Comparative Partisanship*

The study of partisanship as a social identity has also been conducted in non-American contexts. Bankert, Huddy, and Rosema (2017) use a similar partisan social identity scale as that used in the United States to measure the strength of partisan social identity in European

multi-party systems. They find that in the Netherlands, Sweden, and the United Kingdom this identity-based scale is useful for measuring partisan social attachments and is better than a measure of ideological intensity (both identity and issue-based) at predicting inparty voting and political participation. In newer southern European democracies, partisanship is generally less strongly related to social identity and more to evaluation of party performance—a more instrumental outcome (Lisi 2014).

However, in a non-European context, Conroy-Krutz, Moehler, and Aguilar (2016) find evidence of partisan influence on voter decision-making in Uganda, a new multi-party system, while Carlson (2016) identifies strong partisan social identity and partisan motivated reasoning in the same nation. In Brazil, Samuels and Zucco (2014) find evidence that party identification can influence policy positions (counter to the assumptions of normative democratic theory), even in a relatively new democracy with a fragmented party system.

2.3. The Limits on Impartial Partisan Reasoning

One important implication of the identity-based nature of partisanship and ideology is that identities tend to alter assessments of reality and decision-making in a way that benefits the ingroup at all costs. This biased reasoning can generate seemingly “irrational” political behavior—in which voters privilege the status of the party over their own well-being.

2.3.1. *Motivated Reasoning and Inaccurate Beliefs*

Partisan motivated reasoning is a process by which partisans seek out information that is beneficial to their party, and disregard or counter-argue information that harms their party or lowers its status (Redlawsk 2002; Taber and Lodge 2006; Petersen et al. 2013; Lodge and Taber 2013; Leeper and Slothuus 2014). Importantly, these effects are most common among those who are the *most* informed about politics and scientifically literate (Kahan et al. 2012; Lewandowsky and Oberauer 2016). Attempts to provide correct information to partisans can sometimes generate a boomerang effect—whereby strongly identified partisans react to party-inconsistent information with increased commitment to the party line (Redlawsk 2002; Hart and Nisbet 2012; Zhou 2016). Partisans may also, when confronted with undeniable evidence of bad news for their party (like an economic collapse or a terrorist attack), shift the blame for the bad news away from their party toward some other cause (Bisgaard 2015; Healy, Kuo, and Malhotra 2014). Even evaluations of objective economic conditions can be biased by partisanship (Rogers 2016; Enns and McAvoy 2012). Furthermore, these biased and mistaken beliefs are not attributable to “partisan cheerleading”—individuals seem to sincerely believe these motivated beliefs (Peterson and Iyengar 2021).

It is possible to counteract these motivations. By prompting partisans to consider civic duty or accuracy over partisanship, some partisans can overcome some of these biases (E. Groenendyk 2013; Bullock 2009; Bolsen, Druckman, and Cook 2014). Removing a discussion from the political sphere and encouraging open-mindedness can also reduce motivated reasoning (E. Groenendyk and Krupnikov 2021).

However, many partisans do not know the accurate story of who makes up the other party. Americans tend to overestimate the number of partisans who are members of politically salient groups (Ahler and Sood 2018). People substantially overestimate the percentage of Democrats who are union members, LGBT, Black, and atheist, and also overestimate the percentage of Republicans who are Southerners, over 65, Evangelical, and earn more than \$250,000 per year. These misperceptions are significantly greater when a partisan is estimating these numbers for their opposing party. According to Ahler and Sood (2018), these beliefs are associated with allegiance to the inparty and animosity toward the outparty. When people are told the correct percentages, however, they see members of the other party as less extreme and feel less socially distant from them. There are similar effects on policy attitudes—partisans believe their opponents to hold much more extreme policy attitudes than they do in reality—and that belief increases the attitude extremity of those who believe it (Ahler 2014; Levendusky and Malhotra 2016). These inaccurate beliefs about the characteristics of the outparty have real consequences for partisan conflict. For more information on partisan misinformation see Miller and Young (Chapter 16, this volume).

2.3.2. *Partisan Bias in Non-Political Realms*

Partisan identities do not only bias partisans in their evaluations of political reality, but they can also have effects on individuals' decision-making outside of the realm of politics. Bias against outgroup partisans has been observed in the sale of football tickets (Engelhardt and Utych 2020), distribution of college scholarships (Iyengar and Westwood 2015), ratings of personal interactions (Healy and Malhotra 2014), a prisoners' dilemma game (Balliet et al. 2018), college admissions decisions (Munro, Lasane, and Leary 2010), choosing romantic partners (Klofstad, McDermott, and Hatemi 2013), hiring (Gift and Gift 2015), choosing teammates (Lelkes and Westwood 2016), ratings of physical attractiveness (Nicholson et al. 2016), and neighborhood preferences (Hui 2013).

Recent research has even found dehumanizing effects of partisanship and ideology—with strongly identified partisans and ideologues believing that those in the outparty or opposing ideology are less than human to some degree (Crawford, Modri, and Motyl 2013; Cassese 2021; Martherus et al. 2021; Pacilli et al. 2016; Kalmoe and Mason 2022). Dehumanization is a significant risk factor for intergroup violence and conflict (Bandura 1999; Kalmoe and Mason 2022). This type of partisan bias goes beyond what the “Michigan School” conception of partisanship outlined. While a partisan identity can be a useful heuristic or an organizing tool for political behavior, it can also, under the wrong conditions, become a far more extreme influence on political behavior—even extending to political conflict.

By thinking about partisanship and ideology from an identity-based perspective, it becomes easier to explain more extreme political behavior.

3. MULTIPLE IDENTITIES

Having examined the potential biasing effects of partisan and ideological identities individually, it is important to take into account that any individual can and does hold multiple

social identities at any given time, and that the relationship between these identities can increase or decrease the biasing power of these social attachments (Roccas and Brewer 2002). This idea has appeared independently in political science and social psychological research. I will explain each independently and then synthesize the implications for politics.

3.1. Cross-cuttingness in Political Behavior

In the study of American political behavior, social identities can reduce the biasing effects of partisanship and political activity if they are “cross-cutting” or act as “cross-pressures” (Lazarsfeld 1944; Berelson 1962; Campbell et al. 1960; Lipset 1981). Robert A. Dahl (1967) wrote,

A society offers a number of different lines along which cleavages in a conflict can take place; differences in geography, ethnic identification, religion, and economic position, for example, all present potential lines of cleavages in conflicts. If all the cleavages occur along the same lines, if the same people hold opposing positions in one dispute after another, then the severity of conflicts is likely to increase. (pg. 277)

When, for instance, partisanship and ideology grow increasingly aligned, as they did in American politics in the later 20th century (Levendusky 2009), the conflict between the parties is likely to grow increasingly intense (Mason 2015). As other social identities such as race and religion also divide by party, partisanship grows even stronger (Mason 2018b; Powell 1976).

When, however, partisans are exposed to cross-cutting social networks, they tend to grow more politically tolerant (Mutz 2002; Mutz and Mondak 2006), engage in less partisan-motivated reasoning (Klar 2014), engage in higher quality political thinking (Erisen and Erisen 2012), consume less partisan media (Scacco and Peacock 2014), and think of themselves in more non-partisan terms (Lupton, Singh, and Thornton 2015). They also tend to participate less in politics (Nir 2005; 2011; Brader, Tucker, and Theriault 2014). Here we have something of a normative conundrum. Cross-pressured partisans are less hostile to their partisan opponents, but they are also less active in politics altogether.

3.2. Identity Complexity in Social Psychology

Psychological theory supports the findings from political science on cross-cutting identities and cross-pressures at the individual level. Roccas and Brewer (2002) identified the concept of *identity complexity*, which goes beyond the study of a single social identity and instead looks at the relationship between multiple identities—and its implications for outgroup tolerance. In this work, high-complexity identities are those in which a single individual is a member of two (or more) groups and perceives the membership of the two groups to be relatively distinct. In other words, most of the members of one group are not perceived to also be members of the other group. Low-complexity identities are those in which a single individual is a member of two (or more) groups whose membership they perceive to be largely overlapping—most of the members of one group are also perceived to be members of the other group. In contrast with the political science work, this theory depends on subjective

perceptions of alignment between groups rather than the objective assessment of intergroup affiliations.

High-complexity identities tend to encourage tolerance of outgroup members, as the individual identifies with people who are like them, but also unlike them in some way. Low-complexity identities decrease tolerance of outgroup members because the individual does not consider themselves to be similar to people unlike them and has more constrained boundaries around their own identity. Brewer and Pierce (2005) measured the complexity of national, religious, occupational, political, and recreational social identities—finding that individual differences in the perception of the complexity of these identities significantly predicted tolerance of ethnic outgroups. Miller, Brewer, and Arbuckle (2009) found low identity complexity to be correlated with implicit and explicit racial attitudes, closedmindedness, low need for cognition, conservatism, and nationalism.

3.2.1. *Cleavage Structures in Comparative Perspective*

The comparative perspective on multiple identities tends to rely on a more macro view of the effects of “cross-cutting cleavages.” At a societal level, scholarship demonstrates a significant relationship between the alignment of social and political identities and broad intergroup conflict (though for a critique, see Franklin 2010). In a study of 102 countries, Selway (2011a) finds that cross-cutting ethnic and religious identities decrease the likelihood of civil war. Gubler and Selway (2012) find that civil war onset is nearly twelve times less likely in societies where ethnicity is crosscut by class, geographic region, and religion. Scarcelli (2014) specifies that civil war is most likely in the presence of overlapping social cleavages in addition to catalysts such as economic decline and adverse regime change. From a macro-level perspective, the individual dynamics of social group attachment are played out on a global scale.

Altogether, considering the relationships between multiple identities can provide considerable insight into how individuals behave politically and how entire societies can be affected by the convergence or divergence of identities on a mass scale.

4. POLARIZATION

Much like partisanship and ideology, polarization as a concept has long been defined in policy-based terms. The traditional view of polarization in the United States meant that Democrats were becoming more extremely liberal in their policy attitudes and Republicans were becoming more extremely conservative in their policy attitudes. However, it is possible to think of polarization in identity-based terms. Rather than policy attitudes moving further to the ideological extremes (issue-based polarization), polarization can be thought of as group-based conflict (affective polarization). In this view, Democrats and Republicans hate each other not entirely because they disagree on policy, but also because of identity-based conflicts. This section will look at the rise of “affective polarization” in the study of political behavior.

4.1. Affective versus Issue-Based Polarization

A description of affective polarization begins in the United States, where the concept was developed and has been widely researched. However, emerging research has looked at this phenomenon in other countries, and that will be described after the US case. In short, affective polarization describes a scenario in which partisans of two parties dislike each other, in a way not rooted in policy-based disagreements.

Prior to the study of “affective polarization,” political scientists in the United States were engaged in a debate over whether American citizens were polarized at all—using the issue-based definition of polarization. On one side of the debate, the argument was that polarization is only really occurring among our elected representatives and other elite party leaders (Fiorina, Abrams, and Pope 2004, 2008). According to this perspective, most of the electorate was out of sync with elite polarization, and the average American still held moderate issue positions. They argued that much of the increased partisan voting and an increasing correlation between party and ideology that had been observed in recent years was not an indication of polarization, but instead a symptom of partisan-ideological sorting.

On the other side of the debate, a number of political scientists argued that Americans were, in fact, growing steadily and increasingly polarized on issue positions, particularly among politically engaged citizens (Abramowitz and Saunders 2008; Jacobson 2012; Garner and Palmer 2011). According to Abramowitz (2011), among the most engaged voters—those who arguably have the largest effect on national politics, and whose number was steadily increasing, issue polarization was strong and growing.

One of the omissions of this debate was that it did not account for the role of identities in driving partisan animosity. By focusing entirely on whether partisans were polarized in their policy attitudes, the debate missed the fact that many American partisans were very clearly and visibly engaged in intergroup conflict.

What effectively ended the debate was a shift to a focus on the animosity between partisans rather than on whether or not they disagreed. Iyengar, Sood, and Lelkes (2012) published findings that Democrats and Republicans increasingly disliked each other on a personal level, to an extent approximating hatred—a phenomenon that they labeled “affective polarization,” indicating an approach based in partisan feelings. Importantly, they found these effects not only in engaged partisans, but also in non-activists. According to their results, half of Republicans and one third of Democrats in 2010 would feel unhappy if their son or daughter chose to marry a member of the opposing party. Members of both parties negatively stereotyped members of the opposing party, and the extent of this partisan stereotyping had increased by fifty percent between 1960 and 2010. This personal dislike and prejudice, Iyengar et al (2012a) suggested, was only inconsistently founded in policy attitudes, leading them to advocate for a separate measure of polarization, one that is based in the concept of social distance, or group-level animosity, rather than issue position extremity.

4.2. Affective Polarization in the United States

The concept of affective polarization centers identity rather than issues in partisan conflict. Though measures vary, it generally assesses the degree to which partisans dislike opposing

partisans and prefer people in their own party. This theory implies that rather than policy informing partisanship, it is possible—particularly in a contentious environment—for partisanship to inform policy attitudes (Druckman, Peterson, and Slothuus 2013; Cohen 2003; Barber and Pope 2019; Highton and Kam 2011). This reversal of the traditional democratic theory gives partisan identities more power to directly influence politics. When group identities become the central drivers of political decision-making, group status can influence political decisions to an outsized degree (Achen and Bartels 2016). In the extreme case, partisans may prefer group victory (in elections or legislation) over the greater good of the nation or even the quality of life of party identifiers. This biased reasoning is consistent with warnings from American founders James Madison and George Washington against the “mischiefs of faction” delivered in *Federalist* Paper No. 10 and Washington’s 1796 Farewell Address. They warned that if America were to be divided into political factions, citizens would begin to care more about defeating each other and lose sight of the security of the nation and the American project altogether. This type of polarization can drive powerful wedges between Americans.

Indeed, affective polarization has been steadily increasing in America. While feelings toward partisans’ inparty have remained relatively steady, the warmth of feelings toward the outparty has dropped precipitously (Abramowitz and Webster 2016). So why has this “affective” type of polarization increased in America? Part of the explanation can be found in the changing relationship between multiple social identities in American politics. The Democratic and Republican parties have moved into strong alignment with other powerful social identities such as race, religion, ideological identity, and rural consciousness (Cramer 2016; Mason 2018b). As discussed in Section 3 of this chapter, this “social sorting” has created the opportunity for partisanship to become a powerful driver of political action, intolerance, ethnic resentment, and even violence (Mason 2015, 2018b; Kalmoe and Mason 2022). Instead of voting in order to earn the success of your political party alone, that vote is now connected to the status of a number of deeply rooted identities. The stakes of failure are multiplied.

Group identities can inform or strengthen partisanship, but group feelings in general have an influence on partisanship—not only feelings about the inparty but also feelings about the outparty. Partisans who dislike the social groups associated with the opposing party tend to be more affectively polarized and more strongly partisan (Robison and Moskowitz 2019; Kane, Mason, and Wronski 2021). In the other direction, some scholarship has even identified the effects that partisanship can have on individual social identities. Partisanship can influence religiosity (Margolis 2018) and expressed ethnicity, sexual orientation, and class (Egan 2020). Partisan identities are not only informed by group feelings but also powerful enough to change other social identities.

The racial divide in particular has allowed American partisans to structure their partisan conflicts along pre-established lines of highly charged conflict between White and Black Americans (Valentino and Sears 2005; Tesler and Sears 2010b; Outten et al. 2012; Schickler 2016; Christopher Sebastian Parker and Towler 2019; Christopher S. Parker and Barreto 2013; Westwood and Peterson 2022; Hetherington, Long, and Rudolph 2016). The process of social sorting allowed the Republican Party to represent the interests of White, Christian America, while the Democratic Party was increasingly representing those who wanted to overturn centuries of social inequality. Support for Republican Donald Trump in the 2016 election and Trump administration has been repeatedly linked to racial resentment

(Hooghe and Dassonneville 2018; Luttig, Federico, and Lavine 2017; Major, Blodorn, and Major Blascovich 2018; Schaffner, MacWilliams, and Nteta 2018; Mason, Wronski, and Kane 2021). Kalmoe and Mason (2022) found that the most “radical” partisans (those who vilify and dehumanize outgroup partisans) are Republicans who are high in racial resentment and hostile sexism, and Democrats who are low in racial resentment. This pattern suggests that most extreme partisan animosity is rooted in disagreements over the traditional social hierarchy. This type of divide is not easily corrected—Democrats and Republicans have opposite and incompatible visions of who holds power in American society.

Evidence of affective polarization in the United States is rapidly accumulating (for an overview see Iyengar et al. 2019). Miller and Conover (2015) demonstrated that those with strong partisan identities held the most hostile and uncivil political attitudes and were the most active in politics. As explained in Section 2 of this chapter, partisans are increasingly discriminating against outgroup partisans, even in non-political realms, and to a degree that rivals racial discrimination (Iyengar and Westwood 2015), though see Westwood and Peterson (2022) for evidence that race and partisanship are not independent identities.

However, some work has pointed to the weaknesses of some of the assumptions underlying the concept of affective polarization. Druckman and Levendusky (2019) note that observed levels of affective polarization depend on the measure chosen. Common measures include the difference between party feeling thermometers (Lelkes and Westwood 2016), party trait descriptions (Garrett et al. 2014), party trust (Levendusky 2013), and a set of “social distance” measures indicating a person’s comfort having friends or neighbors in the opposing party, or having a person’s child marry someone from the opposing party (Levendusky and Malhotra 2015). Here, the social distance measures seem to be assessing a more behavioral element of affective polarization and do not correlate well with the other measures. The social distance measure (at least the marriage item) also conflates dislike of outgroup partisans with dislike of partisanship in general. Many Americans do not want their child to marry anyone who identifies as any kind of partisan and discusses politics (Klar, Krupnikov, and Ryan 2018).

Furthermore, Druckman and Levendusky (2019) find that when subjects are asked questions about the opposing party in general, they tend to think mainly about the party’s elite actors—prominent political figures (consistent with the “prototype” focus of self-categorization theory). This undercuts the idea that these measures are mainly assessing animosity between citizens. In fact, (Klar and Krupnikov 2016) identify a substantial portion of Americans who are embarrassed to admit their partisan identities and are turned away from politics due to the intense disagreement and animosity on display in public political conflicts.

A related theory is “negative partisanship”—the idea that American voting is driven by negative feelings toward the opposing party, rather than the divergence between inparty and outparty feelings (Abramowitz and Webster 2016). In this perspective, outgroup dislike leads to ingroup loyalty—rather than ingroup affection leading to outgroup dislike (as social identity theory would predict). However, Zhong et al. (2008) note that it may be possible to generate a “negational identity”—in opposition to another group—under conditions that maximize individual need for distinctiveness. Bankert (2021) empirically separated negative and “positive” partisanship (the latter being equivalent to partisan social identity), to examine their independent effects on political behavior. She found positive partisanship

to uniquely predict political participation, while negative partisanship uniquely predicted opposition to bipartisanship.

4.3. Affective Polarization in Comparative Perspective

Evidence of affective partisan polarization has emerged far outside of the American context. Of particular interest is whether partisan affective polarization can behave the same way in a multi-party system as it does in America's zero-sum two-party system. Overall, it seems that affective polarization is not a uniquely American phenomenon. Defining affective polarization as "resentment toward political opponents," Gidron, Adams, and Horne (2020) look at 19 Western countries over 25 years and find that American affective polarization is not more extreme than in other countries, but it has increased more quickly than what was observed in other Western countries since the 1990s.

Reiljan (2020) finds evidence of affective polarization in 22 European democracies—most intensely in central eastern and southern Europe, where the degree of affective polarization exceeds that of the United States. Northwestern European countries, in contrast, are found to have lower levels of affective polarization than the United States. Interestingly, Reiljan (2020) also finds evidence that high levels of affective polarization can be present in countries with ideologically centrist party structures and can be weak in ideologically polarized political systems—reinforcing the independence of issue-based and affective polarization.

Consistent with a theory that group identities can form around divisive political opinions (McGarty et al. 2009), Hobolt, Leeper, and Tilley (2021) identify affective polarization in the United Kingdom around "Brexit" opinion groups. They do not observe affective polarization between parties, but instead between those who voted for the United Kingdom to remain a part of the European Union, and those who voted to leave.

The effects of affective polarization include rising partisan social distance in Spain (Viciana, Hannikainen, and Torres 2019), the perception of politics as a high-stakes competition in 34 countries (Ward and Tavits 2019), and gridlock and democratic erosion in 11 countries (McCoy and Somer 2019).

In terms of mechanisms that drive polarization, political identity centrality was shown to increase affective polarization in New Zealand (Satherley, Sibley, and Osborne 2020). In Turkey, partisan identity drives the perception that the opposing party is a threat (Laebens and Öztürk 2021). A lack of cross-cutting identities is also related to affective polarization in 11 countries—but only when it is encouraged by "political entrepreneurs" who benefit from national division (McCoy, Rahman, and Somer 2018; Somer and McCoy 2019). Finally, affective polarization in 19 Western countries is linked to unemployment and inequality, elite conflict over cultural issues like immigration or national identity, and majoritarian electoral institutions (Gidron, Adams, and Horne 2020).

Due to the novelty of the study of affective polarization outside the American context, nearly all of the studies mentioned above used unique methods of measuring affective polarization. The standard American measures do not perfectly fit a multi-party system. Rather than seeing this as an empirical problem, I interpret this diversity of measures—and their similar conclusions—as a strong validation that affective polarization is an important phenomenon outside of the United States. The only methodological caveat is that in Norway, affective polarization toward parties is lower than in the United States, but affective

polarization toward partisans is indistinguishable from the United States (Knudsen 2021). This suggests, consistent with Druckman and Levendusky's (2019) research, that much of the observed partisan animosity in comparative perspective may be driven by feelings toward elites more than feelings toward regular outgroup partisans.

4.4. Effects of Identities on Emotions and Action

Strong and polarized political identities can powerfully influence political behavior. Brader and Gadarian (Chapter 6, this volume) go into detail on the relationship between emotions and political behavior. Here, I look more closely at the role of identities in guiding emotions and behaviors. One of the main links between identity and emotions or behavior is a threat to the status of the group. When a group's status is threatened (even if only in relation to another group) group members respond emotionally and are motivated to take action to combat the threat (Mackie, Devos, and Smith 2000).

In Section 1 of this chapter, I explained intergroup emotions theory—which specifies that group members can feel emotions on behalf of their group, and that the degree of identification with the group can affect the type of emotion they feel (E. R. Smith and Mackie 2015; Eliot R. Smith, Seger, and Mackie 2007). Strong identifiers respond to group threats with anger, while weak identifiers respond to group threats with anxiety. Huddy, Mason, and Aarøe (2015) applied this theory to partisan social identities—finding that the most strongly socially identified partisans tended to respond with anger to party status threats, but not to issue-based threats. These strong partisans also reacted with more enthusiasm to party status victories, and not to issue-based victories. Anger and enthusiasm are important emotions because they tend to promote action (Marcus, Neuman, and MacKuen 2000).

It is important to note that these emotional reactions are similar for Democrats and Republicans in American politics. When it comes to threats to partisan status, partisans of both parties are equally reactive to status threat. Despite prior findings that conservatives are more responsive to threat (Oxley et al. 2008), more recent research has found that liberals and conservatives likely respond to status threats in similar ways (Crawford 2017; Bakker et al. 2020).

The relationship *between* identities can also affect emotional reactions to threats. Partisans with few cross-cutting identities are more likely to react to threats with anger and to victories with enthusiasm (Mason 2016). Those with many cross-cutting identities, however, do not react with any emotion to these same messages.

Anger and enthusiasm brought on by identity-based engagement in politics can motivate political action including talking to others about politics, wearing a campaign button or putting up a political yard sign, attending political events, and donating money to a candidate or party (E. W. Groenendyk and Banks 2014). Angry partisans are also more likely to engage in partisan motivated reasoning, while anxious partisans are less inclined to do so (Weeks 2015; E. Groenendyk 2016).

Strong partisan identity is also a direct predictor of political action (Huddy, Mason, and Aarøe 2015), but under certain conditions it can be more likely to lead to political participation. For low-status groups, political participation is most likely if they understand their group to be in a subordinate social stratum, think of their group as lacking in social influence compared to another group, and also believe that this subordinate condition is due

to unfair social barriers (Miller et al. 1981). According to Klandermans (2014), collective political action including protest behavior is more likely if the group identity is explicitly politicized. This process occurs when group members are aware of shared grievances, an external enemy is blamed for the group's grievance, and the group seeks to win support from authorities or the general public in their struggle (Simon and Klandermans 2001; van Stekelenberg and Gaidytė, Chapter 26, this volume). The effect of partisan identity strength on election turnout can also be moderated by other politicized identities—such as racial and ethnic identities (Valenzuela and Michelson 2016). In the presence of multiple politicized identities, the effect on turnout is dependent on the strength of all of the politicized identities.

In a more dangerous direction, if strong identities are severely threatened, they can motivate dehumanizing and even violent behavior. As I discussed in Section 2 of this chapter, when group members grow morally disengaged from a particular outgroup, the chance of intergroup violence increases (Bandura 1999). Moral disengagement removes the self-regulatory mechanisms governing moral (non-harmful, compassionate) conduct by dehumanizing and vilifying outgroup members (Bandura 1996). Kalmoe and Mason (2022) identified trends of increasing moral disengagement among American partisans between 2017 and 2021. They found a significant relationship between moral disengagement and support for political violence among American partisans—particularly among those who tend to be aggressive in their non-political lives. They also found that a strong partisan social identity is a consistent predictor of both moral disengagement and approval of partisan violence—the latter of which is prevalent in between 10 and 30% of Americans, depending on the level of partisan threat in the political context. Reducing the likelihood of intergroup conflict is necessary for a stable democracy.

5. PROMOTING AND INHIBITING PARTISAN ANIMOSITY

One of the major concerns raised by new research on the identity-based roots of affective polarization is how to combat it. Political scientists are increasingly looking to theories about intergroup conflict in order to attempt to reduce the increasing animosity on display in the United States and across Western democracies. Though Tropp (Chapter 30, this volume) will cover many of these approaches, they are worth a brief mention here as well.

5.1. Contact Theory

One of the oldest approaches to reducing intergroup conflict and prejudice is as simple as spending social time with members of the outgroup (see Tropp and Dehrone, Chapter 29, this volume). Allport's (1954) landmark research on prejudice identified certain types of social contact that were most likely to reduce intergroup prejudice and conflict. This contact should place members of both groups in equal status and in pursuit of common goals; should be sanctioned by institutional supports; and should lead to the perception of

common interests and common humanity (pg. 281). Pettigrew et al (2011) further refined this theory to specify that all Allport's conditions do not necessarily need to be met in order to reduce prejudice, and that contact can also reduce prejudice "vicariously," via mass media exposure or friends-of-friends. In the case of intractable conflicts, contact can backfire, increasing prejudice, but Goldenberg et al. (2017) have found that changing perceptions of outgroup malleability can increase intergroup cooperation even in these intractable conflict scenarios. Cross-cutting political discussions can also reduce affective polarization (Amsalem, Merkley, and Loewen 2022). Unfortunately, contact between Democrats and Republicans in the United States has become increasingly rare, as partisans have grown geographically segregated (Cramer 2016; Jacobs and Munis 2019; Brown and Enos 2021).

5.2. Superordinate Identity

Another classic approach to reducing intergroup conflict is to emphasize a superordinate group identity (Sherif and Sherif 1953). In the context of politics, a national identity is superordinate to partisan identities. When a nation is under threat from outsiders, it can generate a "rally-around-the-flag" effect, reducing partisan animosity and unifying citizens in defense of the nation and in support of their leader (Mueller 1973). Increasing the salience of a shared superordinate identity can increase communication across groups (Greenaway et al. 2015), and has been shown to reduce affective polarization in the United States between Democrats and Republicans (Levendusky 2017). In western Europe, for example, the global COVID-19 pandemic (a threat to all of humanity) increased trust in government and support for leaders (Bol et al. 2021). A similar effect was observed in Haiti (Lupu and Zechmeister 2021).

However, a threat to a superordinate identity cannot always improve intergroup relations—at times it can worsen conflict. In particular, when there is little trust between groups, and contempt or fear between them, group members may respond to a common threat by scapegoating and blaming the outgroup rather than cooperating (Brewer 1999). In fact, the rally effect from the COVID pandemic was blunted by partisanship in the United States, where interparty tensions were already high and the pandemic response was politicized (Shino and Binder 2020).

5.3. Elite Rhetoric

Political elites have a powerful role to play in reducing or enflaming partisan animosity. Partisans in the public respond to elite polarization by expressing higher levels of affective polarization (Banda and Cluverius 2018) and relying more strongly on partisan cues to form opinions about policy (Druckman, Peterson, and Slothuus 2013). Partisan leaders' willingness to compromise can affect mass partisans' willingness to compromise on political matters (McLaughlin et al. 2017). Elite incivility can incite anger in the mass public (Gervais 2017) and a combative form of partisanship (Gervais 2019). Political leaders even have the power to reduce approval of political violence among partisans (Kalmoe and Mason 2022). One reason political elites have such influence on voters is that they can shape what voters understand as the prototypical group member. By observing leaders, partisans are taught

which norms and values are most important to the group. The public enforcement (or lack thereof) of those norms can shape the behavior of loyal partisans.

5.4. Social Norms

Social norms are generally defined and enforced via social sanctions (Fehr and Fischbacher 2004). Conformity with group norms attracts peer approval and feelings of pride, while deviance from group norms leads to disapproval and feelings of shame (Suhay 2014). To the extent that groups enforce norms of tolerance and cooperation, interparty animosity can be restrained. However, the opposite is also true—norms of extremism and intolerance will evoke a political environment full of conflict. Social reform can indeed occur when new injunctive social norms (“what should be”) work together with identity to amass support for new movements. (L. G. E. Smith, Thomas, and McGarty 2015). To the extent that parties and partisans enforce pro-democratic and anti-extremist norms, hot political tempers could be cooled.

6. CONCLUSION AND FUTURE DIRECTIONS

The role of identity in political behavior often helps to explain voter behavior that may appear to be irrational or normatively problematic. In this chapter, I introduced some of the more common theories of social group formation and cohesion. Most of the work on political behavior relies on social identity theory or one of its offshoots. In general, we think about political behavior as maximizing the status (overall or relative) of our social groups. Crucially, many strongly identified partisans are motivated to sacrifice their own well-being in order to increase or defend the status of their social groups.

By applying this reasoning to partisan and ideological identities, it becomes easier to explain seemingly irrational and normatively problematic behavior from partisans. Strongly identified partisans and ideologues are not necessarily driven by their policy preferences—in fact their policy preferences can be affected by their group identities. In the presence of status threat—which is nearly constant for parties in any democracy—partisans look for status-based victory. Every election is a referendum on the relative status of the parties—and the more biased a person’s political perception is, the more they will believe that victory is essential.

These effects of identity are only compounded when other identities become involved in political conflict. Whether from an objective individual perspective, a subjective individual perspective, or a macro-level society-wide perspective, identities aligned along the same political divide tend to increase animosity, intolerance, political action, and even violence. These types of alignments can generate intractable conflicts within a nation—generating opposing visions for the meaning of national identity.

As the intensity of political conflict increases, partisans can grow more socially distant from each other. Instead of simple disagreements over issues, the involvement of multiple identities can generate a polarization rooted in feelings rather than rational policy considerations. This “affective polarization” has increased rapidly in the United States but

can also be found to varying degrees in many nations across the world. Democracy is not only about choosing legislators to enact policy—it also relies on much more primal feelings of “us versus them.” Although this is contrary to normative democratic theory, it is also important to understand and assess. Without an identity-based understanding of democratic politics, many of the normative assumptions underlying political predictions and expectations will be incorrect.

Redefining the role of identity-defensive political behavior as predictable and common is a project that is only beginning. Future avenues of research may include an examination of the potential benefits of social sorting and partisan animosity—including the possibility of increased political power for under-represented social groups. More research is needed on the potential for democratic partisanship to drive extremism and political violence—in both the American and comparative perspective. Identity-centered interventions should be made more apparent in projects aiming to preserve and maintain democracy. The structural issues of racial, ethnic, and gender-based inequalities only preserve and maintain long-entrenched status hierarchies that will respond to political attempts to equalize with aggressive defensiveness. Democracies should approach reform with that threat in mind. Identity-based politics presents a challenge to normative theories of democracy—but any attempts to ensure a fully-representative multi-ethnic democracy will not be successful until these motivations are taken into account and explicitly addressed.

CHAPTER 25

THE GAZE FROM BELOW

Toward a Political Psychology of Minority Status

EFRÉN O. PÉREZ AND BIANCA V. VICUÑA

“What about groups on the bottom rungs of society’s ladder?... What will they then do, given that they, too, are presumed to prefer a positive... self-concept?”

—Rupert Brown, Social Identity Theorist

IN 1971, the famed social psychologist Henri Tajfel and his collaborators published an imaginative platform of studies now known as the *minimal group experiments*. Their goal was to uncover the basic cognitive principles behind intergroup conflicts. To nab these mechanisms, Tajfel and his team reasoned they had to start backwards: by eliminating the disorderliness of the world and begin introducing, one by one, the complicating factors that would ultimately produce intergroup conflict. This feature is what made their experiments so *minimal*.

It would turn out to be a misnomer of sorts, for the parsimonious mechanisms that Tajfel and his colleagues landed on would prove seminally instructive. We will soon get to these basic “moving parts” of social identity theory (SIT)—the name given to Henri Tajfel’s lifework. But we highlight here one tenet that would prove especially revealing for subordinated groups, or minorities: our chapter’s focus. This is the notion that all humans, regardless of race, gender, sexuality, or other stigmatized attributes, are driven to uphold a *positive self-concept*. This means that in our quests to validate ourselves, group identity is but one channel to cement our self-images.

In principle, this idea makes sense: we identify with others who make us feel and look good. But in practice, complications quickly arise, with most arising from the tension underlined by the opening epigraph: how *do* minorities, who must contend with their subordination, attain a positive identity? The real answer is that SIT’s original formulation was unequipped to directly address this query. In early renditions, what mattered most was the division between ingroups and outgroups, not whether these groups were equals.

A political psychology of minority status, then, must start from the premise that intergroup inequities exist (Craig and Phillips, Chapter 23, this volume). This underscores one way that minorities feel and think differently than dominant groups: they are highly attuned to their subordination, to the point that it can be cognitively and emotionally taxing for many of them (Crocker and Major 1989)—a core insight that applies to minorities who are racial (e.g., Branscombe et al. 1999; Brown et al. 2000; Garcia Bedolla 2005; Pérez 2015a, b), sexual (e.g., Remedios and Snyder 2015; Flores et al. 2018; Goh et al. 2019), religious (e.g., Malliepaard and Verkuyten 2018; Verkuyten et al. 2019; Verkuyten et al. 2019), linguistic (e.g., Laitin 1977; Tavits and Pérez 2019), and others. This laser-focus on one's unequal rank means minorities are quite sensitive to questions about their subordination and threats of old and new forms of oppression (Major and O'Brien 2005). The rest of this chapter explains what this implies for a *political* psychology of minority groups, especially in terms of their attention to civic issues, their opinions and perspectives about public affairs, and their willingness to mobilize toward collective political ends through protest and voting.

To this end, we first expose the systemic roots of minorities' subordination and the psychological motivations these unleash among group members, answering why minorities are, in fact, minorities? We then turn to a robust discussion of key affective and cognitive processes known to govern inter- and intra-group relations. We draw heavily on social identity theory (SIT) and its offshoots (for additional discussion of social identity theory see Mols et al., chapter 22; Mason, Chapter 24, this volume). Although not the only theoretical "game in town," SIT is one of the more well-developed psychological frameworks to study groups (Huddy 2013)—and, also poorly understood by many political scientists (Huddy 2001). Our contribution here is to better align psychology's generic understanding of groups with political scientists' deeper knowledge of specific minorities (Pérez 2021; Pérez and Kuo 2021). We accomplish this by first discussing key psychological threats that all groups experience and how these can propel minorities to express more (less) unified political opinions and greater (weaker) collective action, including group-led protests and bloc voting. We then apply these insights to three (3) literatures we think can benefit from greater attention to the political psychology of minority status: *intersectional identities*, *interminority solidarity*, and the *boundaries between minority-majority groups*.

Although we can spend entire volumes discussing the unique experiences of sundry minority groups, we believe there is much to be gained—conceptually and theoretically—by taking a panoramic view of minorities and identifying those mechanisms that likely cut across specific groups (Pérez and Kuo 2021). Thus, our essay places less weight on group differences and leans heavier toward integrating conceptual insights that can apply *throughout* many minority communities. In doing so, we seek to clarify some core concepts and processes that should allow scholars to better grasp *when*, *why*, and *which* minorities becomes politically engaged in terms of the opinions they express and the actions they undertake.

1. WHAT MAKES MINORITIES, MINORITIES?

It is tempting to think that minorities' station in any society is driven by their relative size, with smaller groups qualifying as minorities. Yet the correspondence between

numbers and status is looser than many presume. Consider how women are treated as minorities, *despite* demographic parity with men (Prewitt-Freilino et al. 2012; see also Bos and Schneider, Chapter 19, this volume). Moreover, in the United States, people of color are labeled minorities, *in spite* of growing demographic, economic, and political clout (Pérez 2021). In contrast, sexual minorities are a small proportion of most populations, yet are aggressively relegated to second-class citizenship (Lewis et al. 2017). These and other complex realities belie an impoverished conceptual vocabulary to explain minority status.

We stipulate that minority status stems from a group's subordination, which is produced by *stigmatization* and *marginalization*. While often used synonymously, we use these terms to underscore two distinct features that yield subordination. This subordination, we hasten to add, is not innate to minorities. It is driven by hierarchies between groups (Craig and Phillips, chapter 23, this volume). Accordingly, to say that minorities are *stigmatized* is to say that they are deemed socially inferior. As Major and O'Brien (2005: 395) explain, the "stigmatized have . . . an attribute that marks them as different and leads them to be devalued in the eyes of others." These stigmas can be (in)visible (*sexual orientation*), (un)controllable (*stuttering*), appearance-based (*weight*), or ascribed (*race*) (e.g., Goh et al. 2019; Garcia Bedolla 2005; Steele et al. 2002). Because stigmas assign minorities a lower social value, it corrupts their positive self-concept.

Minority status is also produced via *marginalization*, or an experienced power deficit. By power, we mean a person's control over their own outcomes (cf. Brehm 1993; Fiske 1993; Goodwin et al. 2000; Richeson and Ambady 2003). Although marginalized group members have personal agency, their complete influence over social and economic outcomes is hindered by systemic forces that emanate from a dominant group's hostility or indifference toward them (e.g., Brewer 1999; Jackman 1994). With less power in hand, *marginalization* further undermines minorities' ability to attain a positive self-concept.

In our view, attainment of a positive self-concept is harder to produce when one is *stigmatized* (i.e., socially devalued) and *marginalized* (i.e., relatively powerless). This is another key difference between dominant and subordinate groups. Dominant group members are driven to *preserve* their relative cachet and power, yet minorities are motivated to *repair* the deficits they face on these fronts. Here, minorities will sometimes use political means to clear a smoother path to a positive self-concept. But we say *sometimes* because political engagement is personally costly (Downs 1957; Riker and Ordeshook 1968). It requires mental energy (Gailliot et al. 2007). And, it often demands extensive resources (e.g., time, money) (Verba, Schlozman, and Brady 1995; Hersh 2020). Hence, there is nothing automatic about minorities' political mobilization, especially given that *stigmatization* and *marginalization* are psychologically painful for minorities—so painful, in fact, that disengagement is a plausible response (cf. Crocker and Major 1989; Vignoles et al. 2006; Verkuyten et al. 2019). Thus, predicting when collective action is more likely starts with a deeper understanding of the psychological motivations that compel any group to mobilize, while clarifying why those efforts manifest *politically* (Olson 1965; van Zomeren et al. 2004; Fowler and Kam 2007). Let us demonstrate this next.

2. FUNDAMENTAL GROUP PROCESSES FOR MINORITIES

As two scholars who study minorities, each of us has been privy to the complaint by some colleagues that they find political psychology too highly abstracted. Yet this complaint entirely misses the goal of robust psychological theory, which is to isolate and validate the core mechanism(s) responsible for individual behavior across varied settings and protagonists. Abstraction is the aim—and virtue. To make this abstraction more palatable, we now draw on social identity theory (SIT) to explain four key mechanisms that are highly relevant to a deeper understanding of minority politics: *categorization*, *distinctiveness*, *identification*, and *ingroup favoritism*.

SIT recognizes that all individuals, even minorities, belong to multiple groups. That is, we have a repertoire of identities where we store memberships in many nominal categories like *race*, *ethnicity*, *gender*, *religion*, and *sexual orientation* (Margolis 2018a; Verkuyten et al. 2019; Pérez et al. 2019; Remedios et al. 2020; Pérez 2020). SIT insists, however, that people do not generally have the mental bandwidth to think of themselves, simultaneously, as members of all their groups. Rather, people manage their complex self-concepts based on contextual cues. “Who” we are at any one time depends on “who else” is around. This is where *categorization* matters.

People’s environments structure the classification of individuals into ingroup(s) and outgroup(s). This categorization can happen through meaningful criteria or arbitrary distinctions (Tajfel et al. 1971; Billig and Tajfel 1973). Indeed, in Tajfel’s minimal group studies, individuals were categorized on the basis of over-/under-counting dots and preferences for abstract art, leading to the creation of an “us” and “them.” The lesson here is that out of the many idiosyncratic traits that individuals possess, systemic forces—for example, institutions, political elites, researchers—*categorize* people using a closed-set of attributes (Horowitz 1985; Chandra 2012; Mora 2014).

In light of *categorization*, individuals become psychologically invested in their ingroup’s *distinctiveness*. Distinctiveness is what makes an ingroup unique and special (Brewer 1991; Branscombe et al. 1999; Malliepaard and Verkuyten 2018; Pérez et al. 2019). It consists of the many attributes and norms that define who “we” are and how “we” should behave. And, since we all seek a positive self-image, individuals strive to ensure this distinctiveness is infused with cachet. *Distinctiveness* is a byproduct of an intergroup setting, not an innate ingroup quality. Consider how in Mexico, the category *Mexicans* is a badge of pride. But if we shift north to the United States, *Mexicans* are drenched in stigmas (Pérez 2015a; Garcia Bedolla 2005). The category is unchanged, yet the frame of reference affects the valence of attributes that comprise it (Chandra 2012).

With *distinctiveness* intact, several doubts are dissipated for individuals. Who belongs in the group? Which group members better reflect the category and which members have a tenuous foothold in it? How are group members expected to behave and what are they supposed to believe (e.g., Ellemers et al. 1999; Schmitt and Branscombe 2001; Reid and Hogg 2005; Danbold and Huo 2015; Margolis 2018a, b; Malliepaard and Verkuyten 2018; Margolis

2018a, b; Verkuyten 2018; Verkuyten et al. 2019)? In a complex world where buzzing streams of information outstrip our cognitive capacities, the *distinctiveness* of an ingroup provides its members with meaning, security, and direction. By clarifying an ingroup's boundaries and essence, *distinctiveness* minimizes the perceived variance between ingroup members, increases the perceptual distance between ingroup members and the outgroup(s), and thus cements ingroup identification (Turner et al. 1987; McGarty et al. 1992). Although the distinctiveness of ingroups can emerge organically, at least in politics, it is often structured by institutions and individual actors, as exemplified by the racial and ethnic categories that national censuses highlight (Nobles 2001; Mora 2014; Rodriguez-Muñiz 2021), as well as the political actions and rhetoric expressed by political leaders through anti-immigrant discourse and initiatives across the globe (e.g., Pérez 2015a, b; Sniderman and Hagendoorn 2007; Santa Ana 2002; Chavez 2001). This point is especially important for minorities. Some scholars lament how the creation of groups (e.g., *Latinos* in the United States) obliterates nuances between its members (e.g., *Mexicans*, *Cubans*, *Puerto Ricans*) (Beltrán 2010). Normatively, we cannot disagree with this. In this particular case, individuals arrive to the United States as *Mexican*, *Cuban*, and *Puerto Rican*, but become *Latino* partly because the US census and other institutions privilege this pan-ethnic category at the expense of other national-origin options—and in contradistinction to other groups (e.g., *White*, *Black*, *Asian American*). Empirically, however, this is precisely what SIT would predict when disparate individuals coalesce into a larger group: identification perceptually homogenizes an ingroup, while increasing its psychological distance from an outgroup (Turner et al. 1987).

Ingroup *identification* can be more precisely thought of as the cognitive and emotional significance that a person attaches to a category (Tajfel 1981; Tajfel and Turner 1979; for a related discussion on political identities see Mason, Chapter 24, this volume). This significance has several components (Leach et al. 2008), but a core element is a category's *centrality* or *importance* to a person: that is, to what degree does a category reflect my sense of self? This is an individual difference, not a type. It is not the case that individuals either identify with a group or not, but rather, they identify with a group to a measurable degree. These individual differences determine which individuals are sensitive to intergroup stimuli and events (Ellemers et al. 1997; Ellemers et al. 2002; Verkuyten and Yildiz 2007; Leach et al. 2010; Pérez 2015a, b; Margolis 2018a, b; Cvetkovska et al. 2020). Thus, to grasp an identity's impact on individual behavior, we must grapple with the differences separating high- from low-identifiers.

In fact, ignoring these nuances comes at the risk of misunderstanding SIT's fourth process, *ingroup favoritism*. This is the inclination to cognitively and affectively privilege one's ingroup with respect to an outgroup(s), including deeper and more detailed processing of information related to an ingroup (Van Bavel et al. 2008) and greater willingness to help ingroup members (Dovdio et al. 1997). In the minimal group studies, ingroup favoritism manifested itself in patterns of reward allotments between the ingroup and outgroup, with ingroup members maximizing the difference in amounts awarded between groups. But ingroup favoritism can also manifest as ingroup members expressing more positive feelings toward one's ingroup (relative to the outgroup) (Branscombe et al. 1999; Pérez 2015a, b; Cvetkovska et al. 2020), endorsing more positive stereotypes about one's ingroup (relative to the outgroup) (Kinder and Kam 2009; Malliepaard and Verkuyten 2018), or supporting public policies or ideologies that privilege one's ingroup (relative to the outgroup) (Block 2011; Margolis 2018a, b; Verkuyten 2018). Yet the bigger insight about *ingroup favoritism*

is not the spread of ways it expresses itself, but rather, its unerring focus. Ingroup favoritism privileges “us,” which is often divorced from any antipathy toward “them” (Brewer 1999). This is critical, because it suggests that being pro-minority does not entail automatic rejection or hostility toward outgroups. One can be pro-Black, without being anti-White (Herring et al. 1999). One can be pro-Latino *and* pro-American (Pérez et al. 2019). And, one can be pro-Muslim, without being anti-European (Verkuyten et al. 2019).

3. IDENTITY THREATS IN LIGHT OF STIGMATIZATION AND MARGINALIZATION

We have stressed, so far, that minorities’ *stigmatization* (devaluation) and *marginalization* (powerlessness) compromise their attainment of a positive self-concept. Consequently, we believe minorities are motivated to recognize and seize opportunities that improve on these dimensions. Some of these opportunities arise from identity threats that minorities encounter. Sometimes, minorities will resolve these threats politically. We illustrate this by discussing four common threats at the intergroup (*value* and *distinctiveness* threat) and intragroup (*categorization* and *prototypicality* threat) levels.

3.1. Value Threat

Value threats impugn an ingroup’s cachet. Any stimulus here that undermines this cachet jeopardizes an ingroup’s *value* for members. Because minorities are subordinated, they are exposed to *value* threats more regularly than are members of dominant groups. This means minorities will be, on average, more sensitive to denigrating stimuli and ready to contend with them. Consider, here, how people of color (Aronson et al. 1998; Steele et al. 2002), females (Shih et al. 1999; Major et al. 2003), LGBTQ individuals (Flores et al. 2018; Goh et al. 2019), and other minorities must manage discrimination against them and their group (Oskooii 2016, 2020).

Although dominant group members may devalue and discriminate against subordinated communities, minorities highly value their ingroup because it provides them with certainty, security, and belonging (Brewer 1991; Branscombe et al. 1999; Pérez et al. 2019; Brannon and Linn 2021). Thus, in light of *value* threat, the generic response is to reinvigorate the ingroup’s cachet through available means, with those more strongly identifying with an ingroup engaging in more vigorous action (since they stand to lose the most, cognitively speaking). For example, in a set of papers on US Latinos, Pérez (2015a,b) demonstrates how *value* threat (operationalized through elite rhetoric highlighting “illegal” immigration) spurs high-identifying Latinos to repair their ingroup by expressing more intense support for pro-Latino policies and greater pro-Latino sentiment. Additional research also traces *value* threat to increases in civic engagement and voter turnout among Latinos (e.g., Gutierrez et al. 2019; White 2016), while other scholarship has reported young Latinas protesting SB4—a Texas anti-immigrant law—by wearing their *quinceañera* dresses, thus signaling ethnic pride as a response to devaluation of their co-ethnics (González-Martin

2020). This is a broad pattern that generally replicates among other “real world” minorities, including ethnic, religious, tribal, and racial ones across the globe (Horowitz 1985; Leach et al. 2010; Verkuyten 2018; Verkuyten et al. 2019; Cvetkovska et al. 2020).

Beyond the specific instances just discussed, this “hunkering down” effect has other effects on minority politics. For example, when a minority identity is impugned, a motivation to defend it is triggered (Kunda 1990; Taber 2003; Taber and Lodge 2006; Taber and Young 2013; Bolsen and Palm 2019), which sidelines other motives, including a drive toward accuracy in judgment. This means ingroup members who sense a *value* threat will engage in reasoning that reaffirms their group’s worth, even at high costs. In western Europe, for example, chronic *value* threats to Muslim minorities (e.g., “Islam is a *backward* religion”) leads them to turn so intensely inward that they dis-identify with their host nation—that is, they actively *reject* a host nation identity, which reduces the amount of common ground that underpins national cohesion (Verkuyten and Yildiz 2007; Malliepaard and Verkuyten 2018; see also Huo et al. 2010; Dovidio et al. 2016). Additional studies suggest this broad effect can have negative downstream consequences for minority political behavior, depending on how *value* threat is transmitted. For example, Oskooii (2020) reports evidence that peer-to-peer discrimination (a form of *value* threat) is associated with reductions in voter turnout among ethnic minorities in Britain. In a similar vein, Komisarchik, Sen, and Velez (2020) find that Japanese individuals who were interned in US relocation camps during World War II expressed less interest in politics two decades after that experience. Thus, while responses to *value* threat are palliative for minorities, they can be detrimental for *inter-* and *intra-*group relations.

3.2. Distinctiveness Threat

Part of how a group retains its cachet is by standing for something positively unique or distinctive. This enables an ingroup to fully differentiate itself from an outgroup(s), which allows ingroup members to bolster their self-image by seizing on the clarity and certainty about what they stand for and what makes them so great. When this distinctiveness is compromised, ingroup members become insecure about who they are. This leads high-identifying members to engage in affective and cognitive efforts to restore that distinctiveness (Ellemers et al. 1999; Danbold and Huo 2015). For example, Pérez et al. (2019) reason that part of what makes US Latinos unique is their balancing of ethnic and national identity—they are *Mexican* and *American*, *Cuban* and *American*, *Dominican* and *American*, and so on. Consequently, political rhetoric that acknowledges this duality affirms Latinos’ distinctiveness. This affirmation motivates Latinos to express greater allegiance to the nation, which they exhibit through attitudes (e.g., *US patriotism*) and preferences (*English as US official language*) that engender greater national unity and cohesiveness.

Distinctiveness threat also provides a window to better understand when racial political coalitions are formed. For instance, ignoring the unique experiences of minority women as racial minorities inhibits the stability of coalitions to address gender inequality (e.g., Cole 2008; Collins 1996). In addition, individuals who possess a dual identity (e.g., *Mexican American*), but perceive discrimination against the stigmatized category in this pair (i.e., *Mexican*), are more inclined to be politicized as a way to improve the disadvantaged position of their minority group (Simon and Grabow 2010; Simon and Ruhs 2008; see also

Pérez et al. 2019). This is further exemplified by Black women's historical position as political organizers across both racial and gender movements (See Michener et al. 2012). On the contrary, respecting a group's *distinctiveness* and sources of pride leads to a greater sense of belonging and cooperation across groups (Brannon et al. 2021). A major lesson here for smoldering debates about multiculturalism and related ideologies is that stable, diverse politics can be sustained through political discourse that acknowledges and respects the distinct identities reflected in a mass public, especially those held by minorities (Huo and Binning 2008; Citrin and Sears 2014).

The principal implication from *distinctiveness* threat is a triggering of ingroup concern over the boundaries and content of the ingroup. This can lead ingroup members to more aggressively police their boundaries, with the goal of reinvigorating the purity of the ingroup (Huo and Molina 2006; Dovidio et al. 2016), which often produces a harsh stance toward ingroup deviants—affiliates who contravene the unique attributes and standards of the ingroup (Marques et al. 1988; Marques and Paez 1994; Pinto et al. 2010). This recoiling from “black sheep” in one's ingroup will generate stronger political cohesiveness among high-identifying group members, as seen in African Americans' sidelining of Black conservatives from their ingroup (White and Laird 2020), the marginalization of later-generation Latinos from their ethnic group's immigrant peers (Jiménez 2010; Garcia Bedolla 2005), and the shaming of Asian Americans who contradict stereotypes about high academic competence (Jiménez 2017).

When an ingroup's distinctiveness is intact, there is more certainty about the ingroup's nature (Reid and Hogg 2005), which yields less variance in the opinions and values expressed by affiliates: two features that facilitate an ingroup's political cohesion (e.g., Block 2011; Hogg et al. 2010; Liss et al. 2001). For example, African Americans, Asian Americans, Latinos, and other minoritized groups are more willing to close ranks, politically, when they sense that their unique histories and struggles are acknowledged and respected (Flores and Huo 2013). In this instance, a shared identity as *people of color* leads these individuals to support policies that do not directly benefit or implicate their own unique ingroup (e.g., Black support for unauthorized immigrants) (Pérez 2021; Pérez, Vicuña, Ramos, et al. 2021). But when these individuals believe the uniqueness of their own ingroup is drowned out for the sake of *people of color*, Asian, Black, and Latino adults are less inclined to support policies that do not implicate their own ingroup (e.g., weaker Latino support for the Black Lives Matter movement).

3.3. Prototypicality Threat

Threats can also emanate from within an ingroup. For example, John Turner and his students (1987, 1994) have taught us that part of what cements an individuals' identification with an ingroup is the sense that one embodies the average, or *prototypical* member. When a minority individual lays claim to being *African American*, *Female*, *Catholic*, *LGBTQ*, and so on, they are professing themselves to be *the* model reflection of their ingroup. If this *prototypicality* is threatened, individuals will mobilize to repair this situation (Schmitt and Branscombe 2001; Wenzel et al. 2007; Danbold and Huo 2015; Danbold and Huo 2017).

One illuminating political example of *prototypicality* threat in action involves White and Laird's (2020) *Steadfast Democrats: How Social Forces Shape Political Behavior*. In this book

the authors contend that African Americans' enduring experiences with racial discrimination have taught them that collective political action is one avenue to improve their social status. Yet such action requires unity in light of political diversity among African Americans, with some leaning ideologically to the left, some leaning ideologically to the right, and plenty of others in between (Dawson 2001). To speak with a more unified voice, Black Americans close ranks by enshrining racial progressives as their ingroup's *prototype*, while shunning explicitly conservative members of their racial group, thus transforming themselves into a steadfast segment of the Democrats' electoral coalition.

In another, now classic, book—*Boundaries of Blackness: AIDS and the Breakdown of Black Politics*—Cathy Cohen (1999) describes Black Americans' tepid response to the AIDS crisis evolving within their communities. Despite the concentration of AIDS cases in African American neighborhoods, Black individuals have politically responded to victims of this disease (some of them homosexuals, some of them drug addicts) with unusual restraint. One way to read this “breakdown” in Black politics, as Cohen describes it, is through the *prototypicality* pressures that ingroups experience. Insofar as Black individuals with AIDS are marginalized and pushed to the periphery of the Black community, it implies that African Americans have defined their prototypical member as male, heterosexual, and “well-to-do,” which underwrites the indifference that Cohen reports (cf. Marques et al. 1988; Marques and Yzerbyt 1988; Marques and Paez 1994).

3.4. Categorization Threat

The last threat we discuss occurs when there is a mismatch between how a person views themselves and how others construe them in a situation. For instance, a female engineer interviewing for a high-tech job might sense *categorization threat* if the interviewer attends more to their gender attributes rather than professional qualifications (Morgenroth et al. 2020). This will lead the threatened female to minimize her gender attributes while amplifying her professional characteristics, even though she may strongly identify as female. Indeed, as Branscombe et al. (1999: 38) explain, “[s]uch resistance to being categorized is likely to be particularly strong when the membership category seems irrelevant or illegitimate given the situation at hand.” In this specific setting, *categorization threat* will prompt female professionals to stress their differences from other female colleagues (Ellemers et al. 1993; Tajfel and Turner 1979).

One example of *categorization threat* in politics is provided by Jiménez (2010), who reports the pressures that some Mexican Americans experience to act “ethnically” in the wake of sustained Mexican immigration into their communities. This influx of new co-ethnics heightens the salience of shared ethnic identity. But for co-ethnics who have been born in the United States and are temporally distant from the immigrant experience, their ethnic identity is often lower in priority, which means some co-ethnics will work to differentiate themselves from their immigrant kin by signaling membership in alternate, higher-status groups (e.g., *Americans*). Consistent with this, Hickel and colleagues (2020) find that some Latinos prioritize their national identity over their ethnic identity, which leads them to express greater support of restrictive immigration policies and hard-right politicians.

Categorization threat also has implications for Republican women in the United States. When a female is mis-classified as a Democrat (or liberal) on the basis of their gender,

it may lead some women to express more conservative opinions about gender inequality in response. Consider the “puzzling” number of White females who voted for Donald Trump—the 2016 Republican nominee for president who publicly espoused sexist views (Junn 2017; Junn and Masuoka 2020). White women breaking for a misogynist candidate is only surprising if we presume that the relevant identity driving these individuals is a *feminist* one—that is, a *politicized* gender identity that only some women hold (Simon and Klandermans 2001; Huddy and Willmann 2016). But identifying as a *woman* does not entail identification as a *feminist*. Alas, women have other political identities that they value more, such as their *partisanship*. Consistent with this reasoning, published research shows that modern sexism played a significant role in women’s support for Donald Trump (Setzler and Yanus, 2018; Valentino et al., 2018), suggesting that the relevant identity driving these individuals was *partisan*, rather than *feminist* (see also Huddy and Willmann 2016).

Beyond this specific case, categorization threat also holds implications for how we might understand the gender composition of elected officials within US political parties. For instance, why do some female elected officials choose to operate as Republicans, rather than Democrats, if the latter is arguably friendlier toward “women’s issues”? Because, our discussion here implies, they may believe that their gender identity is less germane to the type of political work they wish to undertake, suggesting there is more room for maneuver within the Republican Party.

4. GRAPPLING WITH SUBORDINATION THROUGH *POLITICS*

So far, we have tried to give readers a deeper appreciation for some of the basic mechanisms behind a political psychology of minority status. We now use this blueprint to inform—conceptually, theoretically, and methodologically—a trifecta of political science literatures focused on better understanding how minorities deal, politically, with their subordination in intergroup settings: (1) intersectional identities, (2) interminority solidarity, and (3) redefining minority/majority relations.

4.1. Intersectional Identities

Intersectionality, as an analytical framework, calls for a closer examination of the interactive effects of social identities (Al-Faham, Davis, and Ernst 2019; Bos and Schneider, Chapter 19, this volume; Collins 2015; Garcia Bedolla 2007; Hancock 2007; McCall 2005; Nash 2008). Its most notable insight contends that multiply-marginalized individuals experience unique forms of oppression that are fundamentally different from those experienced by their singly-marginalized counterparts. Women of color, for instance, not only experience both racism *and* sexism, but also experience them differently than men of color and White women (Crenshaw 1989, 1991). Many political scientists draw on *intersectionality* to grasp the political behavior of multiply-marginalized communities (e.g., Gershon et al. 2019; Frasure-Yokley 2018; Junn 2017; Labelle 2019; Sampaio 2014). The thrust of this

research is that the unique experiences of multiply-marginalized individuals complicates their ability to prioritize any single identity they hold (Hancock 2007), which suggests that intersectional identities consist of a confluence of categories (King 1988; Settles 2006; see also Wilcox 1996). One implication that follows from this view is that *women of color* might encounter difficulties in cooperating politically with *white women* and *men* if their *distinctiveness* is not acknowledged and respected (Vicuña 2021; Huo and Binning 2008). For instance, scholars of *intersectional* identities have engaged in a long-running debate about whether *Black women* fail to strongly support *feminist* movements because of the latter's *White-centered* image: a highly plausible claim with thin empirical evidence behind it (so far) (e.g., Huddy, Cassese, and Lizotte 2008).

We see standard intersectional approaches to politics as displaying two blind spots: weak conceptualization and loose operationalization of *intersectionality* in political studies (Remedios and Snyder 2015). Both aspects, we think, can be improved through greater attention to the political psychology of minority status. Consider, first, what it means to hold an *intersectional* identity. Does it mean that multiple marginalized categories are simultaneously co-activated in a person (e.g., *female* and *African American* and *homosexual* are synchronously relevant)? Does it mean that multiple stigmatized categories (e.g., *female*, *Latinx*, *homosexual*) are fused together and stored as a single unit in memory (e.g., *homosexual-Latinx-woman*)? The answer to this conceptual point matters for how we understand the nature of *intersectional* identities. For example, if *intersectional* identities are a confluence of chronically activated categories, then this implies a substantial demand for cognitive and emotional resources as one attends to the many ingroups and outgroups in play (Remedios and Snyder 2015; Roccas and Brewer 2002). The risk here is one of being mentally taxed to the point of paralysis. Yet by most accounts, political scientists aspire to use *intersectionality* to better understand political involvement, not *disengagement*. So, what gives?

Part of what has to give are the exceedingly strict assumptions implied by this generic rendition of *intersectionality*. This starts, we believe, with closer attention to how identities are stored in long-term memory (LTM) (Lodge and Taber 2013; Pérez 2016). Psychologists long ago taught us that mental content, like identities, are stored in close proximity to each other in LTM (Collins and Loftus 1975). This means categories like *female*, *African American*, *progressive* are stored near each other in memory, but not so close that they are the same thing. Hence, the categories comprising an *intersectional* identity are correlated, but empirically separable. Indeed, you will recall from our previous discussion on *categorization* that people's information environments relatively privilege one category over many possible others, which suggests that even in studies of *intersectionality*, there is a predominant category that captivates people's attention and directs their behavior, depending on the frame of reference (i.e., who is the outgroup?).

Consistent with this formulation, Remedios et al. (2020) demonstrate that women of color attribute rejection by others to sexism when the outgroup is *males*, but to racism when the outgroup is *Whites*. This pattern suggests that *intersectional* identities adapt to cues in intergroup settings, with the frame of reference being key. Rather than activating a fused *women of color* identity, it appears that several correlated identities are stimulated, with one being relatively more privileged than others in a setting. Similarly, when the frame of reference is doubly an outgroup, like *White men*, women of color anticipate a dual threat to their racial and gender identities (Chaney et al. 2020). This occurs because individuals who

are multiply marginalized are highly attuned to situational cues. They understand the “big picture” about the systemic nature of intolerance.

Conceptually, we think a political psychology of minority status also demands greater specificity about who the frame of reference is for individuals with a heightened *intersectional* identity. This will facilitate efforts to grasp the nature of a politicized *intersectional* identity. Consider the possible differences of opinion among *women of color* if the frame of reference is *White women* versus *White men*. If *White women* serve as the group of comparison, then we might expect stronger political attitudes that improve women of color’s racial disadvantage. If *White men* are the frame of reference, then we might anticipate stronger political opinions that defend *women of color*’s position vis-à-vis *White men*. To gain even further clarity on the nature of responses here, specifying the content of a *woman of color* identity would be valuable (cf. White and Laird 2020; Anoll 2021; Pérez 2021). For example, what does it mean to be a *woman of color* in terms of a prototype and its political values and beliefs (Schmitt and Branscombe 2001; Danbold and Huo 2015)?

Methodologically, a more psychologically informed sense of *intersectionality* entails measuring individual differences in multiple identities and the possible interface between them. This would enable researchers to better assess the reality of various differentiated identities—that is, to what degree is each category in an intersectional identity crucial to the self-definition of a person (Leach et al. 2008)? In an observational context (e.g., opinion survey), appraising identities that “go together” in memory will enable analysts to assess whether they all are associated with outcomes of interest (as an *intersectional* perspective implies), while verifying that one identity has a more “privileged” impact on these dependent measures, consistent with our discussion so far. Insofar as this type of pattern emerges, it would strongly suggest that an *intersectional* identity derives its political power from a convergence of highly valued group attachments, akin to how US partisanship draws force from the confluence and reinforcement of distinct identities (e.g., racial, class, religious, occupational) (cf. Mason 2018; Huddy, Mason, and Norwitz, 2016). In turn, by gauging individual differences in the strength of these identities, researchers can distinguish those individuals for whom various categories are central to their sense of who they are from those for whom these categories are less crucial to their self-image. Those nuances are key to pinpointing who is most likely to “pitch in” to political efforts that prop *intersectional* groups (Ellemers et al. 1997; Leach et al. 2008; Pérez 2015a, b). In particular, it would allow researchers to better appraise whether the political influence of an *intersectional* identity depends on the interaction between relevant categories. For instance, among some *women of color*, their identification as *females* and as *people of color* might simultaneously drive their political views and actions, while for others, the political influence of their *female* identity depends on how strongly or weakly they identify as a *person of color* (or vice versa).

More generally, we believe greater attention to the psychology of *intersectional* identities can break new conceptual and empirical ground. This iterative process begins by distilling one’s reasoning about *intersectional* identities into more concrete, testable, and observable implications (King, Keohane, and Verba 1994). Consider, for example, issues of police brutality or LGBTQ rights. Each of these domains, in principle, broadly implicates multiple nominal categories, such as *race*, *gender*, *class*, and *sexual orientation*. Yet who is energized politically by these issues depends, in no small part, on how they are framed (Druckman 2001; Winter 2008).

By one account, these issues can be framed with a prototypical community member in mind, which, for the purposes of this example, would entail *heterosexual Black men* (police brutality). Per a *galvanization* hypothesis (cf. Sniderman et al. 2004), a subset of potentially relevant categories is politically activated based on key attributes. If this reasoning is correct, then one observable pattern might be an engagement gap, with prototypical members (e.g., *heterosexual Black men*) being more politically aware and knowledgeable than members on the edges of the activated group (e.g., *LGBTQ + Black women*). We might also expect an enthusiasm gap, where prototypical members engage in costlier action on behalf of “their” group than peripheral members. These patterns imply a narrowly politicized core of individuals who are disposed toward collective action, but less inclined toward broad perspective-taking (Adida et al. 2018; Cortland et al. 2017).

By another account, the issues of police brutality can also be framed in a way that allows more variance around a group’s prototype. Per a *mobilization* hypothesis (Sniderman et al. 2004), a wider number of categories is activated based on shared attributes. In the case of police brutality, this entails a focus on race (*Black people*) with less attention to gender (i.e., *Black (fe)males*) or class (i.e., *poorer Black people*). By collapsing across characteristics, more individual group members stand to feel a sense of identification with the activated group. Thus, in terms of engagement and enthusiasm, we might predict smaller or null differences between relevant subsets of ingroup members. And if true, this would suggest a broader, politically energized ingroup that is more uniformly predisposed toward political action. This will matter tremendously in political systems like the United States, where public affairs are conducted on the basis of “large numbers” or coalitions. Furthermore, an ingroup that is more broadly defined inclines members toward greater perspective-taking, since many potential outgroups (e.g., *richer Black people*, *Black females*) are better reflected in the ingroup’s prototype (Adida et al. 2018; Cortland et al. 2017).

In a third account, the issues of police brutality can also be framed with the explicit inclusion of marginalized subgroups (e.g., Black women and Black queer people). Per an *identity respect* hypothesis (Barreto and Ellemers 2002; Dovidio et al. 2016; Huo et al. 2010; Vicuña n.d.), a multiple-identity frame makes non-prototypical members who are committed to other subgroups feel that they are valued, promoting ingroup identification and making them more likely to work on behalf of the larger shared group. In fact, these individuals tend to dislike common ingroup frames because they restrict the ability to resolve intragroup inequalities and tensions, which can fragment the larger group. Black men, for instance, are often perceived as the prototypical victims of racial discrimination, including police brutality (Crenshaw 1989; Jackson 2016; Purdie-Vaughns and Eibach 2008). And yet, Black women have played and continue to play a critical role as political organizers to address racial inequality (e.g., three Black women founded Black Lives Matter) (Michener et al. 2012; Jackson 2016). Black women’s continued involvement in these social movements tells us that, despite not being the perceived prototypical victims of racial discrimination, they have not been discouraged from being politically active (as suggested by the *galvanization* hypothesis). Additionally, the fact that Black women have created more explicitly inclusive movements, like #SayHerName, suggests that their needs are not met by movements with common ingroup frames (as suggested by the *mobilization* hypothesis). Consequently, the political behavior of multiply-marginalized individuals might be better explained by the *identity respect* work, with multiple-identity frames more effectively promoting their political engagement. Future research, then, might find it beneficial to further investigate the

cognitive nature of intersectional identities, especially whether discrete identities interact to form unique political outcomes by reinforcing (or undermining) each other.

4.2. Interminority Solidarity

In a world where many polities are becoming more diverse and unequal, understanding when and how individuals develop solidarity across race, ethnicity, gender, sexual orientation, language, and the like is becoming normatively and scientifically pressing (Jackman 1994; Staerklé et al. 2010; Masuoka and Junn 2013; Flores et al. 2015; Flores, Hatzenbuehler, and Gates 2018; Hasenbush, Flores, and Herman 2019; Michelson and Harrison 2020; Harrison and Michelson *forthcoming*). On the face of it, one might imagine that diversity in the face of inequality is a recipe for the development of solidarity-based movements. Yet one would be wrong, for there is nothing automatic or natural about the emergence of alliances between subordinated groups (McClain and Johnson Carew 2017; Benjamin 2017; Wilkinson 2015). Rather, as the psychology of minority status teaches us, these coalitions take active psychological effort (Pérez 2021; Craig and Richeson 2018). They emerge under specific conditions (Pérez 2020). And, they succeed when minorities are placed in a specific frame of mind (Cortland et al. 2017; Pérez and Kuo 2021).

Take the example of interracial solidarity between various people of color in the United States. Impressions notwithstanding, these subordinated communities vary wildly in terms of their arrival to the United States, their treatment at the hands of US authorities, their experiences with discrimination, and their political aspirations and goals. So how is solidarity stitched together in these contexts? Part of the answer starts with greater attention to the content of identities—especially broad-based identities that can sustain solidarity across disparate groups. For example, research into a *people of color* identity, or PoC ID, suggests this broad-based attachment is characterized by two overarching attributes that unify diverse group members. Through a series of in-depth interviews, Pérez (2021) reports that African Americans, Asian Americans, and Latinos who identify as *people of color* share a common view that their communities are linked because they are structurally disadvantaged with respect to Whites. In other words, official policies—in law enforcement, immigrant admissions, higher education—serve to collectively keep *people of color* “in their place.” Second, these interviews also reveal that *bona fide* PoC view highly progressive, left-of-center politics as *the* key to remedying racial disparities, which implies robust support for an active government hand in nudging citizens toward more equitable race relations.

Both insights align with the experimental insights of Clarissa Cortland and her colleagues (2017). Across five experiments, these authors demonstrate that when groups do not share an identity (e.g., people who identify as *African American* versus *gay*) they will still express solidarity if they recognize common marginalizing experiences (i.e., being discriminated on the count of *race* or *sexual orientation*). Indeed, these findings are consistent with those of Pérez (2021), who shows, experimentally, that PoC ID retains its political influence so long as the various subordinated groups nested under this category feel and think their own minority group’s trials and tribulations are recognized and not “drowned out” by the needs of the larger group.

Achieving solidarity between subordinated groups is therefore quite challenging. Part of the difficulty relates to how inequalities are produced between subordinated groups. The

varied configuration of minority groups means they experience different vulnerabilities. Consider the case of racial hierarchy in the United States. The latest theorizing in social psychology (Zou and Cheryan 2017) contends that Whites are still the most valorized group in America's racial hierarchy. However, major shifts in rankings come from people of color and their respective stations in relation to Whites and each other, as reflected in Figure 25.1. Accordingly, non-Whites are construed as falling along two major axes of subordination. The first of these is the familiar *superior-inferior* dimension that has shaped many political scientists' thinking (Sidanius et al. 1997; Carter and Pérez 2016). Here, Whites are construed as the most *superior* group—that is, the group with the most prestige. Punching right below Whites are Asian Americans: a racial group considered to be higher-status than Blacks and Latinos, but not as socially esteemed as Whites. This liminal station recognizes Asians' more complicated status within America's racial order (Kim 2003; Xu and Lee 2013).

The second axis of subordination, in turn, involves the ranking of groups in terms of how *American* or *foreign* they are considered. Again, Whites occupy the most advantaged position along this corridor (cf. Danbold and Huo 2015; Pérez et al. 2019). Yet among people of color, the jockeying for position along this axis reflects the complex ways in which different racial minority groups experience their subordination. For example, Black people are positioned here as relatively more *American* than Asians and Latinos, who contain many immigrants in their ranks. Thus, in comparison to Asian Americans and Latinos—two groups regularly construed as “foreign intruders”—Black individuals are considered *relatively more American* (Carter 2019).

Notice that in Figure 25.1, each group's position is relative to the other. It is very nearly impossible to understand, say, the position of Asian Americans without also appreciating where African Americans, Latinos, and Whites are located on this plane. In fact, if you look closely, you can better appreciate that each non-White group holds a relatively more privileged rank in comparison to other groups. For example, although many scholars are well aware of the types of advantages that Whites enjoy relative to non-Whites, what has been less clear is how each non-White group enjoys a modicum of advantage with respect

FIGURE 25.1 Two axes of subordination

to other people of color. Although all non-White groups are marginalized, Blacks are stereotyped as a relatively more *American* group than other people of color. Similarly, inasmuch as Asians are stereotyped as a more *foreign* group than Black and White individuals, they are also stereotyped as relatively *superior* to their Latino and Black counterparts. Alas, these small but invidious comparisons can fuel a “narcissism of small differences,” such that any advantage within this hierarchical arrangement, no matter how small or seemingly petty, will trigger the types of intergroup comparisons that often produce ingroup favoritism (Tajfel et al. 1971; Billig and Tajfel 1973).

Consistent with this view, Pérez and Kuo (2021) reveal that threats to minorities’ unique position in the racial order leads them to embrace a defensive posture toward other people of color. In a series of experiments, these authors show that African and Asian Americans will react defensively toward Latinos if they sense this outgroup undermines their group’s more favorable position within the racial hierarchy. For example, Black adults who read about Latinos’ demographic growth perceive changes to what it means to be *American*. Black individuals repair this threat and assert their relative station in the hierarchy by expressing less favorability toward Latinos and other people of color, perceiving less room for cooperation with racial minorities, and indicating greater support for policies that curtail Latinos’ influence (e.g., English-only, immigration restrictions). Asian Americans express a similar defensive posture, but on the basis of a different vulnerability. Specifically, Asian Americans who read about the implications of Latinos’ demographic growth perceive changes to what it means to be a “respectable” immigrant, that is, a foreigner who comes to the United States legally and with higher levels of education and skills. In light of these unsettled perceptions, Asian Americans repair this threat by reporting less favorability toward Latinos and other people of color, expressing a less cooperative spirit with other minorities, and voicing stronger endorsement of policies that curb Latinos’ influence.

Of course, just like the varied social positions of minoritized groups can clarify when two or more communities of color might be less likely to cooperate politically, racial hierarchies also present a variety of psychological opportunities for these groups to also express more unified behaviors and opinions. As Linda Zou and Sapna Cheryan (2017: 698) observe, “Solidarity may be easier to achieve between groups that . . . have similar resulting experiences with prejudice.” Consistent with that view, Pérez, Vicuña, Ramos, and colleagues (2021) reason that people of color who experience a shared source of marginalization will feel a heightened sense of solidarity with people of color, which should then produce more unified political views. For example, although Asian Americans are stereotyped as a *model minority* and Latinos as *low status*, both are viewed as *perpetual foreigners*. In two parallel experiments with Asian and Latino adults, these authors show that reading about another racial group who is marginalized as *foreign* increases Asians’ and Latinos’ solidarity with PoC. This shift, in turn, substantially boosts Asian support for flexible policies toward undocumented immigrants (which implicates Latinos) and Latino support for policies that facilitate admissions for high-skill immigrants (which implicates Asians).

4.3. Redefining Minority-Majority Relations

With so much of our discussion emphasizing hierarchies between groups, it is easy to walk away with the impression that these orders between groups hardly change. But

transformations do occur. And one relevant way this happens is through a re-definition of minority (e.g., *Latinos*, *females*, *Homosexuals*, *Muslims*) and majority relations (e.g., *Whites*, *males*, *Heterosexuals*, *Christians*). We illustrate this point with an analysis of the relationship between *Whites* and *people of color* in the United States.

In the annals of US race relations, observers have grown accustomed to underscoring the durability in unequal relations between (non-)Whites. Yet such persistence does not entail a complete absence of variance. Consider, for example, the previous remaking of *Whites* in light of ongoing demographic pressures that Southern and Eastern European immigrants once presented. Although *Irish*, *Italian*, *Jewish*, and others are considered *White* today, during the early 1900s these groups were considered anything but. Alas, they held a distinct liminal status between “real” *White* and *Black Americans*. The sparseness of survey and experimental data on these liminal groups limits our understanding about the psychological factors that pushed and pulled them toward Whiteness. But historical and sociological accounts suggest at least two parallel explanations. The first is that some members of these immigrant minorities, particularly those in later generations, signaled their worthiness as *Whites* by mimicking the racist attitudes toward *Blacks* that “real” *Whites* used to keep the racial order intact. The second is that prototypical *Whites* (in that era, Anglo-Saxon *Whites*) acquiesced to the claims of some of these *liminal* groups as a way to preserve *White* hegemony. The end result was a sharper hierarchy between *Blacks* and *Whites* that emerged from the incorporation of southern and eastern Europeans into the *White* majority (Wilkerson 2010; King 2000), but as peripheral members—that is, as *White* “light” (Jacobson 1999).

How can scholars draw on these to further our grasp of the psychology of minority status? One way is use surveys and experiments to study contemporary immigrant minorities, such as *Latinos* and *Asians*, and their disposition toward *Whites* and *African Americans*. If transformations in a hierarchy occur when some outgroup members signal their worthiness to ascend into a dominant ingroup, then scholars can seize this insight to explain how some minorities become marginal members of a majority. Part of this stems from recognizing the preservationist logic that drives a dominant group, such as *Whites*: while the contours and content of *Whites* can change, such accommodations seek to retain *Whites*’ perch at the hierarchy’s apex. Remember, although *Whites* may find people of color threatening to their ingroup, this sense of threat from them is not uniform (see Figure 25.1; Zou and Cheryan 2017). Thus, *Whites* might be inclined to give up some *distinctiveness* (by incorporating some people of color, like *Asians* and *Latinos*), while still preserving their dominance (by increasing their distance from *Blacks*). This would imply opportunities for some liminal minorities to exploit for their own interests and goals (see Bonilla-Silva 2004).

To bring some light to these questions, we (Pérez, Vicuña, and Robertson 2023) have argued that *Latinos* are acutely sensitive to social opportunities that let them join a higher status group (e.g., *American*), which provides an avenue to improve their lower rank in America’s hierarchy (Noel et al. 1995; Ellemers and Jetten 2013). In light of these prospects, *Latinos* strive to “prove their worth” as members of the higher ranked group by adhering to its norms and values, which leads them to express political views that bolster the hierarchy’s oppressive efforts. Across five studies composed of surveys and experiments, Pérez et al. (2023) find that *Latino* adults who deem themselves more *American*—a highly esteemed group—express greater prejudice against *Black* people, particularly when *Latinos* feel that their position as *Americans* is jeopardized. In turn, this heightened racism fuels stronger

Latino opposition to affirmative action for Blacks, greater aversion to federal aid to Blacks, and a stronger distaste for monitoring employment-related discrimination against Blacks, among other policies.

5. CODA

If a political psychology of minority status is a scientific goal, then political scientists must start by acknowledging that subordinate groups are mired in inequities. This has been our central proposition. Indeed, despite minorities' stigmatization and marginalization, individuals identify with these ingroups because they reduce the uncertainty of the world by telling members who they are and how they should behave, all while infusing them with a deep sense of belonging. Given that group identities are but one avenue to achieve and maintain a positive self-image, minorities will take advantage of opportunities that allow them to improve the position of their group. This, however, does not always happen in a straightforward fashion. We therefore invite scholars of minority politics to incorporate psychological motivations and processes to more crisply explain and predict minorities' political behavior.

If we have strongly privileged the role of psychology to better understand minorities' political behavior, it is because we think that minorities are complex beings. They recognize the social and structural obstacles that limit their opportunities. They belong to multiple social groups. And, they often possess manifold political interests. Because of this, we cannot summarize their behavior by simply assuming that they invariably act on behalf of only one of their ingroups. We must therefore consider the complexities behind their chosen identities, the content of those identities, and the effects that individual-level characteristics—such as identity strength and prototypicality—have on those identities, all in order to fully understand minorities' political responses. Above all, we must understand that while contextual factors make some identities more salient than others, minorities still have wide discretion and agency to choose the groups they identify with. Indeed, if there is one lesson that you take away from this essay, it is that members of minority groups prefer for their distinctive identities to be recognized and respected, rather than be ignored.

CHAPTER 26

SOCIAL MOVEMENTS AND THE DYNAMICS OF COLLECTIVE ACTION

JACQUELIEN VAN STEKELENBURG
AND TEODORA GAIDYTĖ

THIS chapter is an update of the 2013 chapter *Social movements and the dynamics of collective action* (Klandermans & Van Stekelenburg, 2013). In that chapter we described fundamental social psychological processes—social identity, social cognition, emotions, and motivation—as they were employed in the context of social movement participation and as, we argued, engaging in social movements most of the time implies taking part in some form of collective action. However, the world of protest has changed profoundly since 2013. Virtualization gave the world a new “virtual look,” and we observe as much protest now as in the roaring ‘60s, a decade characterized by high levels of protest activity. It is therefore not surprising that research on the social and political psychology of protest has expanded since 2013, both theoretically and empirically. This chapter is an attempt to synthesize these recent efforts and revise the assessment of where we are. To do so, we refreshed the whole chapter. Therewith the main section of this chapter focuses on social and political psychological approaches to movement participation. The central question is: *Why do some individuals participate in collective action while others don’t?*

This chapter focuses on individuals, addressing central questions concerning their fears, hopes, and concerns. How do people perceive political contexts in ways that drive them to participate or abstain from collective action? What are the choices they make, why do they make them, and what are their motives? These questions center on the individual and therefore belong to the realm of political and social psychology. Obviously, other disciplines like sociology and political science also study social movements and collective action; in this chapter we will adopt a political psychological approach and point to literature from sociology and political science where applicable. Our general assumption is that people respond to the world as they perceive and interpret it. This is what a political psychology of social movements and collective action is about—trying to understand how people respond to perceived sociopolitical configurations. Political psychology explores the causes of people’s thoughts, beliefs, feelings, and actions—and, primarily, how these are influenced

by sociopolitical context. It thus has a lot to offer to the study of protest participation, underscoring the importance of context (van Stekelenburg et al., 2009). This raises additional questions that we also address: How are citizens embedded in their social environment? How do they perceive their political context? How does that influence their political orientation and behavior?

In this chapter, we propose a framework to study the political psychology of collective action participation. We first introduce the dynamics of collective action, which are decomposed into the dynamics of demand, supply, and mobilization (Klandermans, 2004). The dynamics of demand are about people and their motives. The dynamics of supply are about organizations and their appeals. The dynamics of mobilization concern the convergence of demand and supply. In the mobilization section, we specifically consider how classic social capital factors such as social trust and embeddedness in organizations influence who does or does not participate in protest activity. Subsequently we discuss how the social and political psychological processes of politicization, polarization, and radicalization hinder or spur participation in collective action. Finally, we show how perceptions of the political context influence the decision to protest or not, focusing on socio-economic, political, and cultural contextual factors. In doing so, we provide an overview of what social and political psychology, combined with other disciplines, has to offer to the study of social movements and collective action, where we stand, and where we think the lacunas are. We end with a discussion of the challenges by those who study social movement participation.

1. DEFINING SOCIAL MOVEMENTS AND COLLECTIVE ACTION

“Social movements are collective challenges by people with common purposes and solidarity in sustained interaction with elites and authorities” (Klandermans, 1997, p. 2; Tarrow, 1998, p. 4). This definition includes three key elements that deserve elaboration. First, social movements are *collective challenges*. They concern disruptive collective direct action against elites, authorities, other groups, or cultural codes. There is an obvious reason why this is the case. Social movements typically though not always encompass people who lack access to politics (see Craig & Phillips, Chapter 23, this volume). Had they had access, there would have been no need for a social movement. Disruptive collective action forces authorities to pay attention to the claims brought forward. Second, it concerns people with a *common purpose and solidarity*. Social movement participants rally behind common claims; they want authorities to do something, to change a state of affair or to undo changes. Such common claims are rooted in feelings of collective identity and solidarity. Third, isolated incidents of collective action are not social movements. Only *sustained collective action* turns contention into a social movement.

Although movement participants are a minority, several authors have observed that movement types of action have become more frequent over the last 40 years (e.g. Jenkins & Klandermans, 1995; Meyer & Tarrow, 1998; Rucht & Neidhardt, 2002; Van Stekelenburg & Boekkooi, 2013). Others have argued that social movements have become a regular phenomenon in democratic societies (e.g. Goldstone, 2003). Some of these authors have

labeled this trend “movimentization of politics” (Rucht & Neidhardt, 2002), while others coined the term “movement society” (Meyer & Tarrow, 1998), and more recently Miriam Smith (2018) edited a special issue on the promises of the social movement society. This increase in social movement activity is also observed at the individual level, in terms of both protest participation (Dalton et al., 2010), as well as the public acceptance of protest (Park & Einwohner, 2019).

Engaging in social movements most of the time implies taking part in some form of collective action. In the words of Wright, Taylor, and Moghaddam (1990), an individual takes part in collective action “any time that [s/he] is acting as a representative of the group and the action is directed at improving the conditions of the entire group.” Wright (2001) proposes a simple taxonomy of possible forms of political action. In response to some political issue, people can choose to stay inactive; if they get into action, they can engage in individual or collective action; and collective action can be noncontentious or contentious. Participation can further be distinguished in terms of duration (*ad hoc* versus sustained) and effort (weak versus strong) (Figure 26.1).

Some activities require little effort, others a lot, and some are limited in time, while others are unlimited. Activities in the low-effort/limited-duration square typically require large numbers to make any impression on policymakers. It does not make much sense to have a petition with only 10 signatures; you need thousands if not hundreds of thousands. People know this, and thus for them to be motivated, it is important to know that some threshold level will be reached. Therefore, an important element of the persuasion strategy must be how to convince people that enough other people will participate. Activities in the high-effort/unlimited duration square, on the other hand, must solve the free-rider dilemma (see Chong, Chapter 4, this volume). For high-effort/long-duration activities, it usually suffices to have only a few participants who are willing to make an effort. As a consequence, many people can afford to take a free ride. Willingness to participate in this type of activity thus implies readiness to give 90% or more of the supporters that free ride. The social and political psychological dynamics vary, as the story of thresholds and free riders illustrate.

FIGURE 26.1 The process of participation (Klandermans, 1997)

Attempts to explain (non)participation must thus take into account the kind of activity we are talking about.

2. WHY SOCIAL MOVEMENTS EMERGE

In this chapter we concentrate on why individuals participate in movement activities. The question of why social movements come into being, why they become successful or not, or why they have become common practice is not our focal question. There is a rich literature available on that matter (for instance Buechler, 1993; Della Porta & Diani, 2020; McAdam et al., 1996; Meyer & Tarrow, 1998). For our purpose, it suffices to summarize the global answers that have been forwarded, in brief: because people are aggrieved, because people have the resources to mobilize and seize the political opportunity to protest, and because their collective identities politicize. These answers parallel the history of theoretical approaches to collective action.

Research began in the 1950s and 1960s with classical theories such as symbolic interactionism, structural functionalism, and relative deprivation theory. Buechler (1993) classified these theories as classical collective behavior theories, a category that he characterizes as theories that understand social movements as a reaction to social stress, strain, or breakdown. The direct causes of collective behavior are seen as rooted in individuals who are experiencing various forms of discontent or anxiety. Basically, discontent is viewed as the origin of protest. In social movement literature these theories have also been labeled “breakdown theories,” which alludes to the fact that researchers conceived of social movements as indicators of the existence of major cleavages in a society and of societal tension or even breakdown as a consequence.

Resource mobilization theorists saw social movements as normal, rational, institutionally rooted political challenges by aggrieved people. Differential availability of resources explains in their eyes why some aggrieved people become involved in social movements while others do not. It was argued that people need individual and collective resources—money, labor, time, education—to develop efficacy and stage a collective political action. Next to it, there should also be mobilizing agents—organizations and recruiting networks—that facilitate protest participation (McCarthy & Zald, 1977). One of the prominent examples is the US civil rights movement, where the strong indigenous organizations like Black churches provided resources and played a crucial role in the development of Black insurgency (McAdam, 1982).

Resources could be both material and non-material, like connections and social capital one possesses. Within the resource mobilization framework, participation in collective action was analyzed in terms of the costs and benefits associated with it. Rational choice models of behavior (Klandermans, 1984; Opp, 1988) and Olson’s theory of collective action (1965) were employed as models to explain individuals’ participation and nonparticipation in collective action. When the potential benefits outweigh the anticipated costs, people opt to participate. Paradoxically, the same deprivation that might motivate people to stage collective action might deprive them of the resources needed for such action.

Soon a variant of resource mobilization theory developed within political science: the political process approach, which proposed that collective action was driven by

the political opportunities available to aggrieved groups with the resources needed to take action (McAdam, 1982). Political opportunities are “those consistent—but not necessarily formal or permanent—dimensions of the political environment that provide incentives for people to undertake collective action by affecting their expectations of success and failure” (Tarrow, 1998, p. 85). The key recognition, according to Meyer (2004, p. 125), in the political opportunity perspective is that “activists’ prospects for advancing particular claims, mobilizing supporters, and affecting influence are context-dependent. Analysts therefore appropriately direct much of their attention to the world outside a social movement, on the premise that exogenous factors enhance or inhibit a social movement’s prospects for (a) mobilizing, (b) advancing particular claims rather than others, (c) cultivating some alliances rather than others, (d) employing particular political strategies and tactics rather than others, and (e) affecting mainstream institutional politics and policy.” Among the many aspects of the political environment that have been referred to as factors influencing success expectations are the strength of the state, the level of repression, the party system, the degree of access to policy, and the degree to which elites are divided (Meyer, 2004). Kriesi and his colleagues (1995) study these political opportunities by comparing the emergence of new social movements across France, Germany, the Netherlands, and Switzerland. Opportunity structures include the nature of political cleavages, institutional structures, alliance structures (here, the openness and political position of the organized left), and prevailing strategies of social movements. By focusing on the effects of two factors, the configuration of power on the left and its presence or absence in government, they offer a fuller picture of citizen mobilization as it responds to political opportunity. Their study serves to “remind the reader that the state can invite action by facilitating access, but it can also provoke action by producing unwanted policies and political threats, thereby raising the costs of inaction” so Meyer (2004, p. 131).

In the late 1980s and early 1990s, an interest began to develop in the cognitive and affective origins of social movements. In response to the structuralist approach of the then dominant paradigms—resource mobilization and political process theories—social movement scholars from various angles began to highlight the processes of interaction, the symbolic definition and negotiation among participants, opponents, and bystanders of collective action. Grievances, resources, and opportunities are all needed for social movements to develop, but the scholars hold that these factors are also the result of the presence of social movements. They are in the eyes of the beholder and thus socially constructed. Moreover, researchers working from this perspective argued that aggrieved people might have the resources and opportunities to protest, but they still need to construct a politicized collective identity to engage in collective political action.

Over the last three decades, this new approach to collective action has been elaborated in studies of framing, collective identity, and emotions in the context of social movements. Together they have been labeled social constructionist approaches to protest. Snow, Rochford, Worden, and Benford (1986) were among the first to elaborate on the role of cognitive processes in their treatment of frame alignment—that is, attempts by movement organizers to persuade people to adopt the movement’s reading of the situation. The more recent social constructionist studies concern the role of emotions in collective action (Goodwin et al., 2001; Van Troost et al., 2013). At this point, social constructionism has carved out its own niche as a legitimate approach to the analysis of social movements (Buechler, 2000, p. 54).

In sum, breakdown theories, resource mobilization, political process theories, and social constructionist theories all tried to account for the emergence of social movements in our societies. All agree that somehow grievances are at the root of social movements and contention, but they diverge in their explanations of what makes aggrieved people protest. While breakdown theories offer little in terms of mobilization processes beyond high levels of discontent, resource mobilization and political process theory point to resources and political opportunities as factors in the environment that impact on the formation and fate of social movements. Social constructionists, on the other hand, focus more on processes of interaction and sense-making among the aggrieved as internal factors stimulating the emergence of social movements. The remainder of this chapter will be devoted to the mechanisms of engagement in collective action as they are currently conceived in social and political psychology, but we will also draw on the approaches used in political science and sociology literature.

3. THE DYNAMICS OF COLLECTIVE ACTION

The dynamics of collective action can be decomposed into the dynamics of demand, supply, and mobilization (Klandermans, 2004). The *demand side* of collective action concerns characteristics of a social movement's mobilization potential. What is its demographic and political composition? Which collective identities does it comprise? What are the shared grievances and emotions? What is the composition of its organizational field; and to what extent are individuals socially and virtually embedded? The *supply side* of collective action concerns the characteristics of the movement. Is it strong; is it effective? Is it likely to achieve its goals at affordable costs? Does it have charismatic leaders? Is it an organization people can identify with? What does its action repertoire look like? Does it stage activities that are appealing to people? Which ideology does the movement stand for, and what constituents of identification does it offer? Demand and supply do not automatically come together. In a market economy, marketing is employed to make sure that the public is aware of a supply that might meet its demand. *Mobilization* is—so to speak—the marketing mechanism of the movement domain. The study of mobilization concerns such matters as the effectiveness of (persuasive) communication, the influence of social networks, and the role of new media such as the Internet, (smart)phones, and social media.

Studies of participation tend to concentrate on mobilization and to neglect the development of demand and supply factors. Yet there is no reason to take either for granted. To be sure, grievances abound in a society, but that does not mean that there is no reason to explain how grievances develop and how they are transformed into a demand for protest. Nor does the presence of social movement organizations in a society mean that there is no need to understand their formation and to investigate how they stage opportunities to protest and how these opportunities are seized by aggrieved people.

Resource mobilization and political process theorists typically study supply factors, social constructionists study demand factors, and all researchers study mobilization regardless of their approach. We focus in this chapter on the study of collective action in social and political psychology and thus place an emphasis on the demand side of mobilization.

3.1. Dynamics of Demand

Little is known about how exactly demand is formed. A few decades ago Klandermans introduced the distinction between *consensus mobilization* and *consensus formation* (1984, 1988). While consensus mobilization concerns “deliberate attempts to spread the view of a social actor among parts of the population,” consensus formation concerns “the unplanned convergence of meaning in social networks and subcultures” (Klandermans, 1988, p. 175). Gamson (1992) in his book, *Talking Politics*, shows that people use diverse sources of information as they talk with their friends about politics. Employing time-series analysis, scholars such as Vliegenthart (2007) and Muis (2012) demonstrated for the issues of immigration and integration that in a complex interplay between real-life events, media attention, debates in the parliament, and debates between politicians, public opinion is formed and converted into anti-immigrant party support in the Netherlands. Van Stekelenburg and colleagues (2013) investigate how, in a newly built neighborhood, demand for protest develops as a function of the development of formal, informal, and virtual networks. They argue that a collective is needed for consensus to emerge. In fact, only new residents who formed relations with other residents in the new suburb participated in typical not-in-my-backyard (NIMBY) protests. The internet and social media play a pivotal role in creating networks that facilitate consensus formation and the formation of a collective identity, a topic we discuss later in the chapter (Earl & Kimport, 2011; Van Stekelenburg, Anikina, et al., 2013; van Stekelenburg & Klandermans, 2017b).

Indeed, the formation of demand is a process that takes place in social interaction and a perceived social and political context. Individuals are embedded in formal, informal, and virtual networks, which in turn are embedded in multiorganizational fields be it at local, national, or international levels. Understanding the formation of demand in a society requires insight in these processes of consensus mobilization and formation, a subject to which we return in the section on mobilization. Here we will elaborate on grievances, efficacy, identity, and emotions as antecedents of protest participation.

3.1.1. Grievances

Grievances concern “outrage about the way authorities are treating a social problem” (Klandermans, 1997, p. 38). In *The Social Psychology of Protest*, Klandermans expands on this definition to distinguish among illegitimate inequality, suddenly imposed grievances, and violated principles. The notion of suddenly imposed grievances and violated principles originates in the sociological social movement literature. Walsh and Warland (1983) coined the first term and Kriesi (2006) the second. Suddenly imposed grievances—such as the establishment of a waste incinerator or a highway trajectory—are powerful mobilizers, as are violated principles. Illegitimate inequality is dealt with in the literatures on relative deprivation and social justice. Relative deprivation theory holds that feelings of relative deprivation result from a comparison of one’s situation with a certain standard—one’s past, someone else’s situation, or an ideological standard such as equity or justice (Folger, 1986). If a comparison results in the conclusion that one is not receiving what one deserves, a person experiences relative deprivation. The literature further distinguishes between relative deprivation based on personal comparisons (i.e., individual deprivation) and relative

deprivation based on group comparisons (i.e., group deprivation; Kelly & Breinlinger, 1995). Research demonstrates that relative group deprivation is particularly important for engagement in collective action (Major, 1994), but work by Foster and Matheson (1999) suggests that so-called double deprivation, that is, a combination of group and individual deprivation, is even more effective. Based on a meta-analysis, van Zomeren, Postmes, and Spears (2008) conclude that the cognitive component of relative deprivation (i.e., the observation that one receives less than the standard of comparison) has less influence on protest participation than does the affective component (i.e., such feelings as dissatisfaction, indignation, and discontent about outcomes).

Social psychologists have applied social justice theory to the study of social movements (Tyler & Smith, 1998). The social justice literature distinguishes between two classes of justice judgments: distributive and procedural justice. Distributive justice is related to the fairness of outcome distributions. Procedural justice, on the other hand, refers to the fairness of decision-making procedures and the relational aspects of the social process, that is, whether authorities treat people with respect and can be trusted to act in a beneficial and unbiased manner (Lind & Tyler, 1988). Research has found that people care more about how they are treated than about outcomes. Based on these findings, Tyler and Smith (1998) propose that procedural justice might be a more powerful predictor of social movement participation than distributive justice. We can observe these struggles in the Black Lives Matter protests, for instance (Williamson et al., 2018), and that is also what we found both in our research in South Africa (Klandermans et al., 1998) and among migrants in the Netherlands and New York (Klandermans et al., 2008).

Political trust and political cynicism further influence the formation of grievances. There is a lively academic debate regarding the relationship between political trust and protest activity. The debate boils down to the question of whether trust in politics is *positively* or *negatively* related to protest activity. We argued that the question to be answered was not so much whether people who engage in protest activity trust or distrust their political elites, but rather who the trusting and distrusting protesters are and why they protest (Van Stekelenburg & Klandermans, 2018). We exploited a dataset encompassing data on about 9,000 demonstrators whose trust in their parliaments varied widely, ranging from trust-worthy capable, to corrupt incapable. It revealed that distrusting disenchanted citizens turn their back on institutionalized politics, for them demonstrating *substitutes* for the party politics they distrust. Among those high in trust, demonstrating *supplements* party politics. John Jost's research on system justification might be relevant here. Jost and colleagues show that system justification can undermine willingness to protest, even among political activists (Jost et al., 2012). For instance, May Day protestors in Greece primed with a system-justifying stereotype exhibited less anger and willingness to protest compared to a control group of protestors. Future research might dig into the fascinating relation between trust in parliament and justification of the system.

3.1.2. *Efficacy*

It would be hard to deny that people who can be potentially mobilized by a movement are aggrieved, but as we know grievances do not provide a sufficient reason to participate in collective action. Therefore, the key question to be addressed by any grievance theory

is: why do some aggrieved people protest, while others do not? In a later section on the contextual factors that influence protest participation, we delve much more deeply into the role of efficacy, trust, and embeddedness. For the moment, we can simply state that grievances are weak predictors of protest (Dalton et al., 2010). Rather than aggrieved people, it is those who possess political skills and resources who are more likely to protest, independent of their level of grievances. The underlying political psychological concept is efficacy. In political science, individual efficacy (internal and external) and group efficacy (linked to the perceived success of a movement) are distinguished. People are more likely to participate in movement activities when they believe this will help to redress their grievances at an affordable cost (Klandermans, 1984). The more effective an individual believes collective action participation to be, the more likely the person is to participate. Van Zomeren, Spears, Fischer, and Leach (2004) propose efficacy as the core of what they call problem-focused coping—one of the two pathways to collective action they define, the other being emotion-focused coping, with group-based anger at its core (see below on emotions).

3.1.3. *Identity*

Next to efficacy, identity, specifically collective identity, became one of the most important concepts in the social movement literature over the past 40 years. Melucci was among the first to emphasize the significance of collective identity (Melucci, 1989). In the years to follow the concept began to gain prominence in the social movement literature (see for instance Stets & Serpe, 2019; Stryker et al., 2000). Meanwhile, social psychologists began to explore the role of group identification in movement participation (de Weerd & Klandermans, 1999; Kelly & Breinlinger, 1995; Klandermans & de Weerd, 2000; Klandermans et al., 2002; Simon et al., 1998; Stürmer et al., 2003) and concluded that the more one identifies with a group involved in a protest activity, the more likely one is to take part in that activity.

A complicating matter in this respect is the fact that people simultaneously hold multiple identities, while movements tend to emphasize a single identity and refer to a single place in society. As a consequence, people may experience being steered in different directions by conflicting identities (cf. Kurtz, 2002). Individuals might find themselves under cross-pressure when two groups they identify with are on opposite sides of a controversy (e.g., union members faced with the decision to strike against their own company). Indeed, workers who go on strike or movement activists who challenge their government are often accused of being disloyal to the company or the country. This problem is especially relevant in the case of protest participation by immigrants, specifically Muslim immigrants, which can easily be (mis)interpreted as disloyalty to their new country of residence. González and Brown (2003) coined the term “dual identity” to point to the concurrent workings of super- and subordinate identities. They argue that identification with a subordinate entity (e.g., ethnic identity) does not necessarily exclude identification with a superordinate entity (e.g., national identity). In fact, they claim that dual identity is a healthy configuration, as it implies sufficient identification with one’s subgroup to experience basic security *and* sufficient identification with the overarching group to preclude divisiveness.

There is evidence that indeed people who hold a dual identity are more satisfied with their situation than people who do not (González & Brown, 2003; Simon & Grabow, 2010). Furthermore, studies of Spanish and Dutch farmers, South African citizens, and immigrants

in the Netherlands and New York suggest that individuals who report holding a dual identity are more satisfied with their social and political situation than those who do not hold a dual identity (Klandermans, 2001; Klandermans et al., 2004; Klandermans et al., 2008). However, if they are dissatisfied, individuals who hold a dual identity are more likely to participate in collective action.

Most studies investigate how identification fosters mobilization and participation, but the opposite direction—how mobilization and participation strengthen identity formation—is no less interesting (Klandermans & van Stekelenburg, 2019). To do so, we distinguished between deductive and inductive identity formation (inspired by Postmes et al., 2005). Identification with the organizers is formed in a deductive top-down manner via mobilization strategies. The participants bring this existing identity to the protest event. Eventually and inductively, a new activist identity emerges while participants are taking part in the demonstration themselves while sharing grievances with other participants.

Thomas and colleagues (2009) study emerging norms related to ongoing commitment. Drawing on recent developments in the collective action, identity formation, and social-norm literatures, they advance a model to understand sustainable commitment to action. This so-called normative alignment model suggests that one solution to promoting ongoing commitment to collective action lies in crafting a social identity with a relevant pattern of norms for emotion, efficacy, and action. Rather than viewing group emotion, collective efficacy, and action as group products, the authors conceptualize *norms* about these as contributing to a dynamic system of meaning, which can shape ongoing commitment to a cause. These emerging group norms and the previously discussed deductive and inductive identity formation might well play a large role in helping us to understand mobilization and participation in contemporary connective actions organized via social media with minimal organization (e.g., Bennett & Segerberg, 2012). We will come back to these types of actions below.

3.1.4. *Emotions*

Relatively recent work in sociology and social and political psychology has brought emotions to the study of social movements (Goodwin et al., 2001; Van Stekelenburg, 2006; van Zomeren et al., 2019; van Zomeren et al., 2004; see also Brader & Gadarian, Chapter 6, this volume). For those of us who have been part of protest events or watched reports on protest events in the news media, this is hardly surprising. Indeed, it is hard to conceive of protest detached from emotions. Emotions can be avoidance or approach oriented. Fear, which makes people refrain from taking action, is an example of an avoidance-oriented emotion. Anger is an approach-oriented emotion and is known to be an antecedent of protest participation (van Zomeren et al., 2004). There appears to be a relation between emotions and efficacy. When people do not feel efficacious, they are more likely to experience fear; feeling efficacious, on the other hand, is associated with experiencing anger (Mackie et al., 2000). Findings from the study among migrants confirm this: feelings of efficacy reinforced anger and reduced fear, while in their turn anger fostered collective action participation, while fear undermined it (Klandermans et al., 2008).

Van Zomeren et al. (2004) show that anger is an important motivator of protest participation of *disadvantaged* groups. Leach, Iyer, and Pedersen (2006) examined readiness

for political action among *advantaged* Australians to oppose government plans to redress disadvantaged Aborigines. They found that symbolic racism and relative deprivation evoked group-based anger, which in turn promoted willingness for political action. But advantaged group members can also perceive the ingroup advantage as unfair and feel guilt and anger about it. Anger related to in-group advantage, and to a lesser degree guilt, appears to be a potent predictor of protest of advantaged group members (Leach et al., 2006).

In nonnormative violent actions, contempt and hatred appear to be more relevant emotions than anger (Bar-Tal et al., 2007; Becker et al., 2011; Fischer & Roseman, 2007; Tausch & Becker, 2013; Tausch et al., 2008; Van Stekelenburg, 2017). They are a direct reaction to protracted harm perceived as deliberate, unjust, and stemming from an inner evil character of the hated individual or group (see Halperin & Cohen-Chen, Chapter 30, this volume). Shared hate delegitimizes the outgroup and facilitates a clear distinction between the outgroup and ingroup. If feelings of superiority are threatened, fear can undergo a terrible transformation into hatred and violence (Sternberg, 2008). Thus, in sum, we can define two emotional routes to protest (Van Stekelenburg & Klandermans, 2017a): an anger route based on efficacy leading to normative action, and a contempt/hate route when legitimate channels are closed (Wright et al., 1990) and the situation is seen as hopeless, invoking a “nothing to lose” strategy leading to nonnormative protest (Kamans et al., 2011; Matsumoto et al., 2015).

Whereas the importance of anger, hate, contempt, and other negative emotions spurring action are indisputable, relatively little attention has been paid to the role of positive emotions, such as hope, in collective action research (Sabucedo & Vilas, 2014; Tausch & Becker, 2013; Włodarczyk et al., 2017). Sabucedo and Vilas maintain that positive emotions, such as hope and pride, can facilitate protest. Hope, in their words “is related to the expectation that desirable phenomena will happen” (Jarymowicz & Bar-Tal, 2006). The anticipation that the objectives established will be attainable activates hope, and this encourages involvement in the protest. Thus, an emotional climate of hope may provide support for prolonged, targeted group activity in the future” (Bar-Tal et al., 2007). Pride appears to be associated with taking—actions that are social and highly valued by individuals in a specific setting (Tangey et al., 2007), such as acting in line with the values of the ingroup. In this sense, it is linked to the act of participating itself.

3.1.5. *An Integrating Framework*

Strikingly, a comprehensive framework integrating identities, grievances, and emotions into a single model was lacking for a long time. Recently, however, Simon et al. (1998), van Zomeren et al. (2008), van Stekelenburg and Klandermans (2007, 2017), and van Stekelenburg, Klandermans, and van Dijk (2011) have each attempted to build such models. The three models identify different pathways to collective action. Simon et al. distinguish between an instrumental and identity pathway; van Zomeren et al. distinguish between an emotion- and a problem-focused pathway; and van Stekelenburg and Klandermans distinguish among pathways to collective action associated with instrumentality, identity, ideology, and anger. All three models emphasize the central role of identification; in order to develop the shared grievances and shared emotions that characterizes a demand of protest,

FIGURE 26.2 Motivational dynamics of collective action participation

a shared identity is needed. Similarly, all three models include an instrumentality component with efficacy as a key aspect.

Figure 26.2 depicts our summary of the various models to explain the strength of the motivation to participate in collective action. Motivational strength results from group-based anger, and instrumental and/or ideological motivation. Instrumental and ideological motivation each result from grievances and feelings of efficacy shared with a group that the individual participants identify with. Grievances may originate from interests and/or principles that are felt to be threatened. The more people feel that interests of the group and/or principles that the group values are threatened, the angrier they are and the more they are prepared to take part in collective action to protect their interests and/or to express their indignation. However, this motivational constellation might differ across contexts; grievances are also socially constructed and organizers play an important role here, they do their utmost to frame the cause in terms that resonate with their constituency (Van Stekelenburg & Klandermans, 2014). Hence, turning the mobilizing potential into actual participation depends also on the supply of opportunities to act.

3.2. Dynamics of Supply

Social movement organizations are more or less successful in satisfying demands for collective political participation, and we may assume that movements that successfully supply what potential participants demand gain more support than the movements that fail to do so. Movements and movement organizations can be compared in terms of their effectiveness in this regard. This is not to say that this is easy to assess (Giugni et al., 1999; Giugni, 1998). Measures of movement effectiveness differ and include the movement's impact on and access to polity, impact on public opinion, mass media attention, and its ability to provide selective incentives (McCarthy & Zald, 1977; Oliver, 1980). Nonetheless, movement organizations try to convey the image of an effective political force. They can do so by pointing to the impact they have had in the past, or to the powerful allies they have. Of course, they may lack all this, but then, they might be able to show other signs of strength. A movement may command a large constituency, as witnessed by turnout at demonstrations, large or increasing membership figures, or large donations. It may comprise strong organizations with strong charismatic leaders who have gained respect, and so on.

An important element of the supply side of participation is the provision of information about the behavior of others. Social networks—real and virtual—are of strategic importance in this respect because it is through these networks that people are informed about the behavior or intentions of others (Kim & Bearman, 1997; Klandermans & Oegema, 1987; Oegema & Klandermans, 1994; Passy, 2001, 2003). In his paper on the Chinese student movement of 1989, Zhao (1998) gives a striking illustration of this mechanism. He describes how the ecological circumstance that most students in Beijing live in the same part of town made the success of the movement in terms of mobilization visible in the streets in front of the dormitories. It goes without saying that these days the virtual world, and social media such as Facebook, do the same (van Stekelenburg & Klandermans, 2017b). We will discuss social networks as a part of a social capital in the section on mobilization below.

Movements offer the opportunity to act on behalf of one's group. This is most attractive to people who identify strongly with their group (de Weerd & Klandermans, 1999; Kelly & Breinlinger, 1996; Simon et al., 1998; Stürmer & Simon, 2004). Interestingly, these studies show that identification with the more exclusive group of movement participants is far more influential than identification with the more inclusive category. Indeed, in addition to the opportunity to act on behalf of the group, collective action participation offers further constituents of identification: for instance, a charismatic leader of the movement; the movement's cause; the other people in the movement, the movement organization itself, can all function as the source of identification. Not all these sources of identification are always equally appealing. Movement leaders can be more or less charismatic, or the people in the movement can be more or less attractive. Moreover, movements and movement organizations may be, and in fact often are, controversial. As a consequence, movement participants are frequently stigmatized (Klandermans & Mayer, 2006; Linden & Klandermans, 2006). Within the movement's network, this is, of course, completely different, as Stuart and colleagues (2013) show in their study on members of the Sea Shepherds. There militants have the internal status denied to them by society. Indeed, it is not uncommon for militants to refer to the movement organization as a second family, a substitute for the social and associative life society is no longer offering them (Orfali, 1990; Tristan, 1987). Movement organizations not only supply a source of identification, they also offer all kinds of opportunities, such as marches, rituals, songs, meetings, signs, symbols, and common codes, to enjoy and celebrate the collective identity (see Stryker et al., 2000, and Stets & Serpe, 2019, for an overview).

Moreover, social movements play a significant role in the diffusion of ideas and values (Eyerman & Jamison, 1991). Rochon (1998) makes the distinction between "critical communities," where new ideas and values are developed, and "social movements" which are interested in winning social and political acceptance for those ideas and values. "In the hands of movement leaders, the ideas of critical communities become ideological frames" (Rochon, 1998, p. 31). Through processes such as consensus mobilization (Klandermans, 1988), framing (Snow et al., 1986), or dialogue (Steinberg, 1999) movements seek to disseminate their definition of the situation to the public at large. Such definitions of the situation have been labeled "collective action frames" (Gamson, 1992; Klandermans, 1997). Collective action frames can be defined in terms of injustice (that is, some definition of what is wrong in the world), identity (that is, some definition of who is affected and who is responsible), and agency (that is, some beliefs about the possibilities of changing society). We may

assume that people who join a movement come to share some part of the movement's ideas and values.

Social movements do not invent ideas from scratch; they build on an ideological heritage as they relate their claims to broader themes and values in society. In so doing they relate to societal debates that have a history of their own, and that history is usually much longer than that of the movement itself. Gamson (1992), for example, refers to the "themes" and "counterthemes" that in his view exist in every society. One such paired theme and countertheme he mentions is "self-reliance" versus "mutuality," that is, the belief that individuals must take care of themselves versus the belief that society is responsible for its less fortunate members. In a study of the protests about disability payments in the Netherlands, we demonstrated how in the Netherlands these two beliefs became the icons that galvanized the debates (Klandermans & Goslinga, 1996). While "self-reliance" became the theme of those favoring restrictions on disability payments, "mutuality" was the theme of those who defended the existing system. Another example is what Tarrow (1998) calls "rights frames": human rights, civil rights, women's rights, animal rights, and so on—in other words, collective action frames that relate a movement's aims to some fundamental rights frame. For decades, Marxism has provided this kind of ideological frame for social movements.

To sum up, the supply side of collective action is not static or a constant. In fact, it has to be constructed again in every mobilization campaign. McAdam et al. (1996) have defined this phenomenon as *mobilizing structures*, which are "those collective vehicles, informal as well as formal, through which people mobilize and engage in collective action" (McAdam et al., 1996, p. 3). Mobilizing structures are the connecting tissue between organizers and participants.

3.3. Mobilization

Mobilization is the process that gets the action going; demand and supply would remain potential ingredients of action if the process of mobilization did not bring the two together. As mentioned above, social networks, social trust, and communication channels are indispensable to the mobilization process. They are crucial for the emergence of shared grievances, enhanced social connectedness, and the development of perceived collective efficacy.

3.3.1. *The Role of Embeddedness: Social Trust and Social Capital*

The concept of social capital has important implications for advancing our understanding of the role of social embeddedness and social trust in protest participation. In his study *Making Democracy Work* Putnam defines social capital as a possession that does not contain material assets, but connections among individuals: it consists of "features of social organization such as trust, norms, and networks that can improve the efficiency of the society by facilitating coordinated actions" (1993, p. 167). From the civic culture perspective, social trust belongs to a broader set of values that characterize "good citizenship," according to which community-oriented citizens are expected to be politically active, to advance both their own interests and the interests of the community.

Social trust is particularly important for facilitating mobilization processes because it suppresses fear, on the one hand, and enhances political efficacy, on the other. As Benson and Rochon (2004) notice, the costs of taking part in a demonstration may be relatively small, but can result in arrest and prosecution, depending on the democratization of the regime and the atmosphere of the demonstration. Thus, participants need to make a leap of faith to perceive participation in a collective action as worthwhile and effective. Social trust leads to optimistic estimates about the likelihood of success of a protest because it increases the expectation that others will act (Dasgupta, 1988; Gambetta, 1988). In this way, social trust helps to overcome the free-rider problem because individuals trust others to act. In Rothstein's (2013) terms, they develop positive reciprocity. Some studies show that social trust translates into political efficacy, which, in turn, leads to protest participation (Gaidytė, 2015; Gaidytė & Muis, 2019). The reasoning, according to Kerr and Harris (1996), is that people with more cooperative social motives attach greater weight to others' outcomes. Putnam (1993) observed that in a more trusting community ordinary citizens have a greater sense of political efficacy because they feel empowered to influence political issues. In contrast, in distrustful societies people perceive themselves as being exploited, submissive, and dependent, constraining their sense of political efficacy. Similar results were obtained in a study by Bäck and Christensen (2016), who found that social trust enhances the propensity to participate in demonstrations in European countries, and even more so in contexts characterized by higher levels of social trust.

In line with the social capital concept, active membership in organizations and involvement in voluntary associations is considered crucial to the transformation of trust from an individual characteristic to a collective resource. Being embedded in a network ensures that collective material and cognitive/psychological resources are accessed equally by citizens. The emphasis here is on voluntary organizations (within an institutional setting), rather than private circles of friends or family (Klandermans et al., 2008). Formal social networks are thought to function as "schools of democracy" where "citizens learn to participate by participating" (Pateman, 1970, p. 105). Hence, when citizens participate in small-scale civic associations, they are taught habits of cooperation and thus able to socialize into larger political entities actions (Putnam, 1993, 2000; Newton, 1997; Van der Meer and Van Ingen, 2009; Van Stekelenburg et al., 2016).

3.3.2. *The Role of Communication Networks*

The effect of network interaction on protest activity is contingent on the amount of political discussion that occurs in social networks and the information that people gather about politics as a result (McClurg, 2003). Klandermans et al. (2008) provide evidence for such mechanisms: immigrants who felt efficacious were more likely to participate in a protest provided they were embedded in social networks that offered an opportunity to discuss and learn about politics. Being integrated into a network increases the chances that one will be targeted with a mobilizing message and that any promise to participate is monitored and socially enforced.

Indeed, part of the infrastructure of a movement's mobilization potential is the communication networks that connect individuals. Walgrave and Klandermans (2010) demonstrate how open and closed communication channels and weak and strong ties weave a web

of connections that influence how easy or difficult it is to reach a movement's mobilization potential. Polletta, Chen, Gardner, and Motes suggest that the Internet plays an important role in grievance formation (2013). This corroborates van Stekelenburg and Klandermans' (2017b) observation that technologies such as mobile phones, the Internet, Facebook, and so on, played a crucial role in the mobilization of high school students in the Netherlands in a protest campaign against educational policy.

Roggeband and Duyvendak (2013) raise the question of whether traditional networks and organizations such as parties, unions, or churches have lost their mobilizing force and are being replaced by light communities such as Facebook groups and highly fluid mobilizing structures. They suggest that more and more people avoid "heavy" long-term engagements and replace more formal institutions for looser engagements in informal, sometimes temporary, or issue-specific networks. As they also see a change from "identity politics" to "issue politics," these authors suggest that the emergence of "light" communities will be accompanied by a process of individualization resulting in a shift from collective to individual action.

3.3.3. *The Process of Mobilization*

Mobilization is a complicated process that can be broken down into several conceptually distinct steps. As mentioned previously, Klandermans (1988) distinguished between consensus and action mobilization. The more successful consensus mobilization is, the larger the pool of sympathizers a mobilizing movement organization can draw from. In their frame alignment approach to mobilization, Snow and Benford and their colleagues further elaborated on consensus mobilization (see Benford, 1997, for a critical review; and Snow, 2004, for an overview). Klandermans and Oegema (1987) broke the process of action mobilization down further into four separate steps: people (1) need to *sympathize* with the cause, (2) need to *know* about the upcoming event, (3) must *want* to participate, and (4) must be *able* to participate (see Figure 26.3).

Each step brings the supply and demand of protest closer together until an individual eventually takes the final step to participate in an instance of political protest. The first step accounts for the results of consensus mobilization. It divides the general public into those who sympathize with the cause and those who do not. A large pool of sympathizers is of strategic importance, because for a variety of reasons many a sympathizer never turns into a participant. The second step is equally crucial; it divides the sympathizers into those who have been the target of mobilization attempts and those who have not. The third step concerns the social psychological core of the process. It divides sympathizers who have been targeted into those who are motivated to participate in the specific activity and those who are not. Finally, the fourth step differentiates among people who are motivated, dividing them into those who participate and those who do not.

In their research on the mobilization campaign for a peace demonstration Klandermans and Oegema (1987) found that three-quarters of the population of a community south of Amsterdam felt sympathy for the movement's cause. Of these sympathizers, three-quarters were somehow targeted by mobilization attempts. Of those targeted, one-sixth were motivated to participate in the demonstration. And finally, of those motivated, one-third ended up participating. The net result of these different steps is some (usually small)

FIGURE 26.3 The process of action mobilization (Klandermans & Oegema, 1987)

proportion of the general public that participates in protest. With each step smaller or larger numbers drop out, but the better the fit between demand and supply, the smaller the number of dropouts.

3.3.4. *Mobilization with Minimal Organization*

Sometimes the demand for protest can be so overwhelming that very little is needed to bring large numbers of people onto the streets. In Belgium in 1996, Dutroux was arrested on suspicion of having kidnapped, tortured, and sexually abused six girls aged between 8 and 19, four of whom died. A number of shortcomings in the Dutroux investigation caused widespread discontent in Belgium with the country's criminal justice system. In the context of the massive indignation regarding the kidnapping and serial killing of children by Dutroux and judicial errors in Belgium in dealing with it, television and newspapers sufficed as mobilizing actors (Walgrave & Manssens, 2000). Yet the mobilizing power of the media should not be overestimated (Kingdon, 1984). They only have the power to mobilize in the case of so-called consensual issues (Verhulst, 2011), that is, issues that are grounded in suddenly imposed grievances that evoke a communal sense of repulsion and indignation. Examples include the death of a child caused by drunken driving (McCarthy & Wolfson, 1996) or senseless violence (Lodewijkx et al., 2008). The salience and the consensual character of the issues compensate for the lack of organization, making mobilization via the mass media possible.

It is helpful to consider an example of protests staged in the absence of any form of organization (Van Stekelenburg & Boekkooi, 2013; van Stekelenburg & Klandermans, 2017b). In November 2007, 20,000 Dutch secondary school pupils took to the streets protesting the deteriorating quality of their education. The movement took the shape of protests by several groups geographically scattered and occurred over time. The protests were impromptu and short-lived. They were initiated by the stereotypical guy next door, Kevin, whose call for action was “virally” spread via face-to-face personal and virtual networks (e.g., MSN,

social network sites). Via mobile phones, videos of unrest were uploaded on YouTube, and the YouTube videos facilitated frame-alignment. Hence, in real-time, *would-be* protesters came to share grievances and emotions with *actual* protesters, and they shared information on actual turnout.

These secondary school protests are examples of so-called connective action (Bennett & Segerberg, 2012). Mobilization for connective action moves from one person to another—individually, as part of a larger email list, or a social network such as Facebook, Instagram, or TikTok. In a process that continues to reproduce itself, the message is copied and redistributed. An original sender cannot know where or when the message stops traveling, stops being copied and redistributed, stops being translated. Messages with higher degrees of resonance will be dispersed in greater densities. The Arabian revolutions from Tunisia to Syria, the earlier Green Protests in Iran, and the more recent Black Lives Matter, #MeToo, and storming of the Capitol are all examples of the power of connective action.

Mobilization with minimal organization has become more effective with the appearance of virtual networks and social media. This changing form of connectivity affects dynamics of contention dramatically (e.g. Enjolras et al., 2012; Enjolras et al., 2014; Harlow, 2011; Velasquez & LaRose, 2014). Various social media such as LinkedIn, Instagram, and Facebook make it easy to connect to others in a network. Previously this was time consuming, effortful, and thus costly. This implies that anyone can be an organizer nowadays, as exemplified by the young climate change protesters who organized the international Friday For Future movement (Wahlström et al., 2019). Social media have given people a set of tools that allow them to create and find these groups. They reduce the costs of participation by lowering communication and coordination costs and facilitate group formation, recruitment, and retention. As such, they make organizing without organizations feasible (cf. Earl & Kimport, 2011). They can also foster collective identity across a dispersed population; they encourage the perception among individuals that they are members of a larger community by virtue of the emotions, grievances, and the feelings of efficacy they share. And finally, they create networks. These sites—which have attracted millions of users worldwide since their introduction—make it possible to connect to hundreds of people who share interests and activities across political and geographic borders. What makes them unique is not that they allow individuals to meet strangers virtually or in-person, but rather that they enable users to publicly display their connections and make visible their social networks (Boyd & Ellison, 2007). The internet and social media created a new virtual stratum; individuals move around in *virtual* networks in addition to (in)formal *physical* networks.

Social media thus make self-organized action feasible, by on the one hand lowering information, communication, and coordination costs, and on the other hand offering a space and tool to produce, express, and perform political dissent. They help to steer loosely coupled structures (Lacquer, 1999) and make grievances, ideas, and ideologies travel rapidly from one context to the other. The term “CNN effect” has been coined to describe the influence of satellite news on intergroup conflicts in other parts of the world: “The idea is that a global conscience comes into being through the global mass media” (Moghaddam, 2008, p. 128). Through satellite television and the Internet, people are more informed about the struggles of their brothers and sisters worldwide with which they feel emotionally connected. Social media spur intergroup conflict because “explosive import products” such as fights between activists and the police, storming of the Capitol, or Israeli attacks against

Palestinians are vividly transmitted and facilitate the creation of global activist identities such as Black Lives Matter, or Muslims.

The internet and social media also augment activists' tactical repertoire, be it offline actions that are supported and facilitated by the Internet, or online actions that are Internet-based (Van Laer & Van Aelst, 2010). Internet-supported actions involve the Internet as a device that reinforces the traditional tools of organizers by making it easier to organize and coordinate. Smartphones make it possible to continuously document activists "on the spot" about actions and interaction with the police and thereby change the tactics of groups like the "Black Bloc" (McPhail & McCarthy, 2005) and Extinction Rebellion (Shah, 2019). Internet-based action, on the other hand, involves the Internet's function of creating new and modified tactics as for instance online petitions, email bombings, and hacktivism, expanding the action toolkit of social movement organizations.

4. POLITICIZATION, POLARIZATION, AND RADICALIZATION

Today's societies are increasingly described in terms of uncertainties and threat (Moghaddam, 2008), fears (Bauman, 2006), and risk (Beck, 1992). Such collective fear enhances politicization, polarization, and radicalization (Bar-Tal et al., 2007). Perceived threat and social exclusion are said to fuel such political participation especially if citizens do not trust their government to solve their problems (Van Stekelenburg & Klandermans, 2018). However, fear can also reduce polarization under some circumstances—for example, through avoidance of confrontation (e.g. Mackie et al., 2000). The kind of threat that stokes polarization is probably linked to anger (Van Zomeren et al., 2004). Globalization and migration create dynamics that serve to include some and exclude others in a connected but polarized global context. It results in salient identities and ensuing clashes of ideologies (Moghaddam, 2005, 2008). In societies where "threat is in the air" (Moghaddam, 2008), prejudice and hate toward other groups are high (Sniderman & Hagendoorn, 2007; Van Stekelenburg et al., 2010), which provides an opening for political actors to politicize prejudice in order to mobilize for (radical) conflict behavior (Kinnval & Nesbitt-Larking, 2010).

When do people go beyond moderate collective action to choose more extreme, radical forms of action? Research on both conventional collective action and political violence suggests that radical forms of action are usually preceded by more moderate forms of support. In the section on Mobilization, we discussed Klandermans & Oegema's (1987) four stages model of social movement engagement, from being a sympathizer, to becoming an active participant. Similarly, in the political violence literature, scholars have emphasized the incremental nature of engagement in radical action, utilizing a staircase metaphor (e.g. Moghaddam, 2005). Indeed, in both the social movement and political violence literatures there has been a well-articulated need to understand a commitment to collective efforts to bring about social change *as a process* (Horgan, 2008). There are two transformations relevant to understanding the process of becoming a (radical) activist, more specifically: (1) the shift between sympathy and active support (Klandermans & Oegema, 1987), and (2) the shift between support for moderate collective action and more extreme strategies (Stuart

et al., 2013). Three processes are particularly useful for describing these shifts, respectively *politicization*, *polarization*, and *radicalization*. We will discuss these three processes. We argue that politicization and polarization are interrelated but different processes both nested in the process of radicalization.

4.1. Politicization

Awareness of a collective identity does not necessarily make that identity politically relevant; collective identity must politicize to become the engine of collective action. Politicization of a collective implies that people “intentionally engage, as a mindful and self-conscious collective (or as representatives thereof), in a power struggle knowing that it is the wider, more inclusive societal context in which this struggle takes place and needs to be orchestrated accordingly” (Simon & Klandermans, 2001, p. 323). Politicization of collective identity and the underlying power struggle unfold as a sequence of politicizing events that gradually transform the group’s relationship to its social environment. Typically, this process begins with the awareness of shared grievances. Next, an external enemy is blamed for the group’s predicament, and claims for compensation are leveled against this enemy. Unless appropriate compensation is granted, the power struggle continues. If, in the course of this struggle, the group seeks to win the support of third parties such as more powerful authorities (e.g., the national government, or political parties as we could observe when Black Lives Matter aligned with the Democrats in the United States) or the general public, collective identity fully politicizes (Simon & Klandermans, 2001).

What distinguishes politicized collective identity from collective identity? The first distinction is raised consciousness: “the growing awareness of shared grievances and a clearer idea of who or what is responsible for those grievances reflect a distinct cognitive elaboration of one’s worldview providing group members with a meaningful perspective on the social world and their place in it” (Simon & Klandermans, 2001, p. 327). The second distinction is about the relation with other groups. A politicized identity provides antagonistic lenses through which the social world is interpreted. This intergroup polarization defines other groups in the social and political arena as “pro” or “con,” thus as allies or opponents. The third distinction concerns the unique behavioral consequences of politicized collective identity, namely, politicized group members should be likely to engage in collective action directed at the government or the public to force them to intervene or to take sides. This is facilitated by social movement organizers who skillfully design collective action frames that emphasize, who we are, what we are angry about, and whom we hold responsible.

Simon and his students (Simon & Grabow, 2010; Simon & Ruhs, 2008) have argued that a politicized collective identity is inherently a dual identity. Some sense of identification with the superordinate political entity seems to be a basic requirement of social and political mobilization in that it ensures that this entity is acknowledged as *one’s own* social or political habitat or arena. More specifically, to the extent that one identifies with the superordinate entity, one should feel entitled to make political claims, because identity confers rights. Similarly, one should feel motivated to get actively involved in the political game, because it becomes one’s own game, and one should feel encouraged to approach third parties as potential allies, because they can be viewed as in-group members at the superordinate level (Simon & Ruhs, 2008; Turner-Zwinkels et al., 2017).

Little is known about the dynamic processes of politicization of the collective identity and how this may change the content of social identities. Felicity Turner (2017) recently wrote a dissertation on this topic and developed an innovative measure to assess changes in identity content due to politicization. In one of her studies, she examines politicized identities among (un) politicized Americans in the 2012 US presidential elections. In a longitudinal sample of US citizens ($N = 760$), they tracked personal (i.e., unique) and politicized (i.e., party activist) identity content: before, during, and after the election. They compared identity content of individuals who self-labeled as politicized (i.e., active party promoters) or unpoliticized (i.e., passive party supporters). Their results show that politicized identities are moralized identities that have a self-evaluative, but not strongly action motivation, function. Methodologically this work is innovative and useful and we are confident that her research will yield results that will move the field forward, especially in understanding the dynamic interplay of individual and context over time.

4.2. Polarization

We live in polarized times. Take Trump, Brexit, or Black Lives Matter protesters clashing with the police. Intergroup conflict occurs in a wider, more inclusive societal context. We conceive of polarization as an instance of movement/counter-movement dynamics in which the ingroup and outgroup “keep each other alive” (Meyer & Staggenborg, 1996). Ingroup and outgroup mutually reinforce each other, identifying themselves in opposition to each other and regarding the other as the main target of their collective actions. When groups polarize, a strict distinction between “us” and “them” evolves. Both groups assert that what “we” stand for is threatened by “them,” tribute is paid to the in-group’s symbols and values, and the outgroup is derogated. It is a *cyclical process* that evolves over time fueled by intergroup incidents. Each incident—like a terrorist attack—generates a push for intragroup similarity and intergroup distinctiveness through which groups drift apart and intergroup conflicts intensifies (Van Stekelenburg et al., 2010). This cyclical process intensifies by exposure to intergroup violence, which increases intolerance, hatred, and feelings of revenge (e.g., Halperin, 2008; see also Halperin & Cohen-Chen, Chapter 30, this volume). The more intense the polarization, the more—and more violent—the associated intergroup conflicts. Polarization—in the sense of opposing opinions—belongs to a democratic society. It gives voice to interests and emotions, and facilitates group formation. However, the balance may tilt, sharpened oppositions lead then to conflict and polarization is threatening rather than enriching. There are compelling reasons to worry about polarization. Indeed, the latest Global Risks Report (2017) ranked “increasing polarization” as third most important risk-trend for the decade to come.

The social sciences approach polarization from different vantage points. As a consequence, what constitutes polarization remains unclear (Esteban & Schneider, 2008). Political scientists primarily investigate the political arena and focus on *political polarization* at the level of political parties. “For parties to be polarized, they must be far apart on policy issues, and the party members must be tightly clustered around the party mean” (Poole & Rosenthal, 2001, p. 105) or at the level of citizens (e.g., DiMaggio et al., 1996; Mason, 2015) In political science much of the emphasis is on affective party polarization not ideological (see Iyengar et al. 2019, for an overview article; see also Mason, Chapter 24, this

volume). Sociologists, conversely, focus on the social and conceive of it as *social polarization*. They focus on structural segregation along ethnic, religious, and class lines in global cities like New York (Sassen, 2016), Amsterdam, and Rotterdam (Burgers & Van der Waal, 2008; Hamnett, 2001). Social sorting is one of the main bases for polarization according to Mason (2016), who focuses on sorting grounded in race, religion, and left-right identification. So it is fair to say that social or group polarization has heavily shaped this research in political science. Social psychologists, finally, study polarization as a phenomenon “in people’s mind.” They describe it as *group polarization* and emphasize the sharpening of group-based attitudes, ideas, norms and group identification (e.g., McGarty et al., 1992). Obviously, in reality these arenas are intertwined. Indeed, political polarization extends to social arenas, erodes social trust (Martini & Torcal, 2016), and takes on the same processes of exclusion, rigidity, and confrontation present in the political struggle (McCoy et al., 2018). Hence, one cannot study the one form of polarization and neglect the other.

The continuation of conflict is facilitated by sustained mistrust (Bar-Tal & Teichman, 2009). This makes *trust* a core concept in polarization (see also Iyengar et al., 2019). This is indeed what we found in a pilot study conducted among citizens of Rotterdam (van Stekelenburg, 2018); the more polarized a neighborhood, the greater the number of reported conflicts (recorded by Police Central Control Room). But neighborhoods with high levels of trust in local politicians, police, and each other reported *less* conflict despite similar levels of societal polarization. This suggests that interpersonal and institutional trust enhance resilience to the effects of polarization, and their vital role in curbing polarization.

4.3. Radicalization

When a movement declines, many activists quit (Klandermans & van Stekelenburg, 2015). But becoming inactive is not the only response to movement decline. Indeed, radicalization appears as an alternative response to movement decline (della Porta, 1995). Although violence tends to be present from the very beginning of a protest cycle, the more dramatic forms of violence occur when the mass phase of the protest cycle is over (della Porta, 1995). Violence as mobilization declines is attributed to people’s dissatisfaction with protest outcomes and their attempts to compensate for the “reduction in numbers” (della Porta, 1995). At the same time the repression apparatus becomes more effective toward the end of a cycle. Against that background, sustained participation can take the form of radicalization, making radical, sustained participation and disengagement different sides of the same coin.

Following social psychologists such as Moghaddam (2005) and Doosje et al. (2016), we consider radicalization to be a *process*. Both scholars depict the process of radicalization as a staircase. Thought and action on each floor are characterized by particular psychological processes. People are located on different floors of the building, but everyone begins on the ground floor. The ground floor starts with subjective interpretations of material conditions, perceptions of fairness, and trust in politics. Individuals try to move up to the first floor, in search of ways to improve their life conditions. These individuals attempt to improve their own situation and that of their group. On this floor, they are particularly influenced by options for individual mobility and voice. When people feel their voice is listened to, they “buy into” the system. Hence, people feel politically efficacious and might participate in lawful protests to voice their grievances. However, when they feel they are voiceless,

they become more dissatisfied and detached. They may then climb up to the second floor, where they come under the influence of persuasive messages telling them that external enemies cause their problems. From this stage on, social movement organizers become important in the process of radicalization. Some individuals keep climbing up to reach the third floor, where they adopt a morality supportive of radicalization. Gradually, those who have reached the third floor become separated from the mainstream norms and values of their society, which generally condemn radical activism. Those individuals who continue to climb up to the fourth floor adopt a more rigid style of categorical “us versus them,” “good against evil” thinking; it is seen as legitimate to attack “the forces of evil” in every way feasible. They take on a view supportive of an “ends justify the means” approach. The group’s isolation is an important factor in explaining its deviation from the “normal” perception of reality and strengthens this tendency toward violence (e.g., della Porta, 1995). Eventually, some of these individuals move up to the fifth floor and take part in and directly support violent actions. The higher people move up the staircase to radicalization, the lower the degrees of freedom. After people have become part of a radical political group, the only options left open to them are to kill, be killed, or be captured.

Social movements are carriers of meaning and organizers and leaders do their utmost to create moral outrage and to provide a target against which this can be vented. They must weave together a moral, cognitive, and emotional package of attitudes. Organizers appeal to “attack emotions” such as anger to create “fire in the belly and iron in the soul” (Gamson, 1992, p. 32). However, just being angry is not enough, as Martin Luther King (1968) aptly stated: “It is not enough for people to be angry—the supreme task is to organize and unite people so that their anger becomes a transforming force.” This is what organizers do—use their power, resources, and creativity to turn individual grievances and emotions into collective claims and to stage opportunities to act upon these claims. In other words, organizers create collective actions frames that turn individual grievances into political claims (van Stekelenburg, 2014). They use discourse and identity as resources to emotionally prime members for social movement recruitment. This “emotion work” has always been key to the organization of protest (Schrock et al., 2004), especially in the context of dangerous or risky protest. Fear, for example, may inhibit collective action, and so organizers attempt to frame situations such that fear will be suppressed or at least mitigated (Goodwin & Pfaff, 2001). Moreover, and important in the context of our “emotional work by organizers” argument, Matsumoto and colleagues show, by analyzing leaders’ speeches in different stages, how organizers mobilize different violent emotions at different stages. Through the careful use of language and nonverbal behaviors, leaders motivate, escalate, or defuse situations and incite action through emotion transformation (Matsumoto et al., 2015; Mols et al., Chapter 22, this volume).

5. HOW CONTEXT MATTERS?

Individuals cannot be seen as independent from context, thus many of the approaches and analytical levels of collective action discussed in this chapter point directly or indirectly to the influential role of external social and political factors. Why are people in some countries more politically active than people in other countries? This question draws our attention to

contextual factors and how they shape the relationship between important individual characteristics and political engagement.

Several studies have already suggested that contextual characteristics—such as perceived corruption (Olsson, 2014), type of political regime (Bernhagen & Marsh, 2007; Hooghe & Quintelier, 2014), institutional effectiveness, inequality, economic growth (Christensen, 2011; Hooghe & Marien, 2013; Van Deth & Elff, 2004), and other institutional conditions, such as the level of political (de)centralization and form of government (for instance, Van der Meer et al., 2009; Vráblíková, 2014)—matter for individuals' decision to engage in a collective action. In short, people experience deprivation and oppression within a concrete setting which translates into specific grievances. The context also provides an array of possible collective response to a grievance. We elaborate next on socio-economic, political, and cultural factors as the most prominent contextual factors shaping an individual's decisions to protest.

5.1. Socio-economic Factors

There are two major pathways by which socio-economic factors could foster protest participation; the first is related to resources and the second to grievances. A dominant perspective of political participation argues that a country's economic growth and prosperity gives people "the luxury" to participate, because, on the one hand, it reduces material insecurities and, on the other hand, enables people to invest more of their time in political issues—this is also what the post-materialist thesis suggests (Van Deth, 1983; Inglehart, 1997). It is argued that the process of economic development leads to social change that also alters the political culture of a nation and that is associated with the rise of new forms of political participation (Nie et al., 1969; Inglehart, 1997; Dalton, 2004). Empirical studies suggest that an increase in the supply of material resources leads to an increased level of protest participation, even among the relatively poor (for instance, Inglehart, 1997). One argument for this is that rich countries generally implement extensive social welfare systems that not only facilitate the development of civic engagement, but also make citizens feel safer (because the system guarantees basic socio-economic needs) and consequently make them more willing to take political action (Van Oorschot & Arts, 2005; Lancee & Van de Werfhorst, 2012).

Inequality is another contextual socio-economic indicator that affects protest participation (Alesina & La Ferrara, 2000; Uslaner & Brown, 2005; Van Deth et al., 2007). In more equal societies, a greater number of people are enabled to embark on collective action. As Lancee and Van de Werfhorst (2011) notice, in more unequal societies people tend to abstain from participation because they feel greater disadvantage and are more anxious than they would have been in more egalitarian societies. In their empirical study, they find evidence that independent of individual resources, higher inequality diminishes social participation. Uslaner and Brown (2005) support the argument by saying that in unequal societies people think that they are not represented; they feel powerless and therefore they engage in less collective action.

In a second explanation linked to grievances, the opposite logic seems more applicable. Increasing socio-economic inequality and economic crisis in general could lead to more perceived grievances and heightened motivation to demonstrate, as seen in the anti-austerity protests and Occupy movement that followed the 2008 global recession

(Van Stekelenburg & Gaidytė, 2021). The worsening economic situation of a country and perceived deprivation can bring people to the streets (Grasso & Giugni, 2016). Della Porta (2015) distinguishes movements of crisis, driven primarily by the victims of the crisis and often more spontaneous and violent, from movements of affluence, primarily composed of conscience participants, better organized, and less violent. She points out that a new social class, the “precariat,” made of unemployed or part-time employed educated youths with no or few social protections, was the main actor in the movements against inequality and corruption (Della Porta, 2015, p. 4). In each context, protesters possess a different set of resources—individual or provided by social movement organizations—that affect their efficacy of participation. Using the demand and supply metaphor of Klandermans (2004), we may assume that grievances and mobilization potential (social networks) become more relevant for motivation to protest than the supply side and shift the protest demand curve upward. In other words, aggrieved individuals are more likely to protest regardless of the participation cost (e.g., risk).

5.2. Political Factors

Political institutions and people’s perceptions of the political context greatly influence individual’s willingness to protest (Kittilson & Schwindt-Bayer, 2010; Christensen, 2011; Marien and Christensen, 2012; Vráblíková, 2014; Gaidytė, 2015). Following Lijphart (1999), a basic distinction is frequently drawn between power sharing and power concentrating democratic systems (Kittilson & Schwindt-Bayer, 2010, p. 991). The power-sharing democracies value inclusion and the representativeness of the political powers and therefore aim to generate governments that are representative of a wide array of interests. Power-concentrating democracies prioritize accountability and the rule of the majority and therefore aim to produce efficient majority governments with clear responsibility for decision-making. The extent of power sharing or institutional openness plays an important role in determining how easy it is for citizens to influence the political decision-making between elections (Christensen, 2011, pp. 59–61). In line with this reasoning, Vráblíková (2014) demonstrates that states with more veto points—more “checks and balances” on political leaders—have more individual protest participation. In a system with more checks and balances, decision-making is less decisive and slower, and protest activists can hope to be successful with their demands.

From the contextual perspective, perceived political corruption is known for two-sided repercussions for collective action. On the one hand, some claim that corruption is a counter-motivator of political participation, including protest, because high levels of corruption decrease perceived political efficacy, making people believe that their actions will not bring about change (Uslaner, 2002; Rothstein, 2013). According to Kostadinova (2012), the negative effect of corruption on protest behavior is strongest in countries that are less or not at all democratic. This moderation effect implies that in less democratic countries, high levels of corruption would deter protest activity whereas higher levels of perceived political corruption mobilize people and bring them to the streets in advanced democracies (still, the former countries would score high on corruption level, while the latter would score lower). However, more recent examples in Belarus and Russia show that aggrieved individuals will still protest, instead of relying on electoral routes to affect politics,

even against corrupt regimes. Nevertheless, these protest activities are not long lasting, and mobilize relatively small numbers of protesters.

Finally, the democratization of a country is also an important determinant of collective action. Drawing from Western countries' experience, participation in social movements increases rather than decreases when societies democratize and governments become more responsive to citizens' claims (Goldstone, 2004). This is congruent with Inglehart's thesis: in democracies citizens develop awareness and criticism against hierarchical institutions and thus are more likely to engage in elite-challenging activities. The opposite is observed in non-democratic countries. Repressive political environments may increase the costs of participation considerably: people may lose friends, they may risk their jobs or otherwise jeopardize their sources of income, they may be jailed, and they may even lose their lives (Ayanian & Tausch, 2016; Davenport et al., 2005; Honari, 2018; Honari & Muis, 2021).

5.3. Cultural Factors

Cultural environment and specific values constitute the third set of contextual effects that drive participation in elite-challenging activities (for instance, Schwartz, 2006; della Porta & Diani, 2020). The cultural context could be defined as the shared beliefs, and meanings commonly found at a place and time. It could be perceived as a cognitive apparatus that people need to orient themselves in the world, and that, in turn, constraints or fosters collective action. Activists' interpretation of their situation, their perceptions of what is worthy and unworthy, and their guiding principles of life are all important to define individuals' capacity to act and their tactics of collective behavior (della Porta & Diani, 2020, p. 64).

From this perspective, certain value orientations and resources, such as social trust, are a property of contexts, not only of individuals; on the aggregate level they create a contextual climate (Kawachi et al., 2008). Almond and Verba in their study *The Civic Culture* (1963) claim that political culture influences whether and in what way individuals will engage in politics. Their study concludes that even those who possess a lower socio-economic status are inclined to actively participate when a democratic civic culture is prevalent. In environments dominated by participatory attitudes, people feel more efficacious about political participation.

In a similar vein, Putnam argued that social trust serves as a "public good" with positive spill-over effects on collective action (Putnam, 1993, 2000). His study of the Italian regions pointed out that democratic engagement works better in an environment characterized by high levels of social capital: "Stocks of social capital, such as trust, norms and networks, tend to be self-reinforcing and cumulative. Virtuous circles result in social equilibrium with high levels of cooperation, trust, reciprocity, civic engagement" (Putnam, 1993, pp. 111, 177). That said, even poorly connected individuals benefit from a well-connected community (Putnam, 2000, p. 20). The reverse is also true: societies can also be locked in a self-producing process of distrust that inhibits participatory motives.

In advanced industrial societies, people participate in new social movements to express post-materialist values of the new middle class. The cultural shift in these societies places an emphasis on such values as self-actualization, quality of life, and expression of collective action (Melucci, 1980). By protesting, individuals engage in so-called new politics, which demands democratization of everyday life, equal rights, recognition and acceptance of

difference (Martin, 2015). Concerns related to climate change and rising inequality create a new demand, mobilizing potential, for social movements in Western democracies. In sum, the economic, political-institutional, and cultural context adds to our understanding of why some individuals engage in collective action while others do not. Context should be part of the explanation because it shapes the way in which social and political processes occur (Tilly & Goodin, 2006, p. 6). However, context should not be overestimated in models predicting protest, because it would carry a risk of misunderstanding the essence of political phenomena, in this case—collective action—located in it. The context should be treated as a surrounding, an affecting condition, rather than a direct cause and the phenomenon of interest itself (Collier & Mazzuca, 2006; Ancelovici, 2021).

6. CONCLUSION

In the chapter, we have reviewed the state of research on collective action, through the lens of political psychology and other disciplines.

We hope it provided useful insights into the study of social movements and collective action. We applied a dynamic theoretical approach which linked the mechanisms of supply and demand sides of collective action. From the demand side, we analyzed the prerequisites of political participation, such as grievances, identification, efficacy, emotions, and a need for social embeddedness. We integrated these concepts to account for the motivation to participate in social movements. From the supply side, we underscored the characteristics of social movements itself, such as the effectiveness of social movements, the ability of organizations to appeal to individual grievances, and the ideals and values on which movements are based. Much attention was paid to virtual, formal, and informal networks, generating participatory motives, and social media, which decreases the cost of participation. We also touched upon the processes of politicization, polarization, and radicalization that stem from (socially constructed) collective fear. Finally, we have contextualized the individual inclination to protest, by discussing socio-economic, political, and cultural factors influencing collective action. We concluded that protests are shaped by context, although we agree that individual action itself and the psychological mechanisms behind it should not be underestimated.

Where do we stand now and what should we expect regarding the development of the study of collective action in the years to come?

First, in terms of formation of demand and supply, the Internet and social media have become increasingly central to the emergence of collective action. Social media obviously facilitates cooperation and helps to overcome the start-up problems of collective action by forming small groups and coalitions that share similar attitudes (Centola, 2013). Pervasive social media thus raises new questions about how it reduces the costs of information acquisition and information processing. Take for instance the traditional information-processing approach focused on the individual. There is growing recognition that cognition forms within social groups rather than within an individual (e.g. Gamson, 1992; Smith & DeCoster, 2000; Taber, 2003). Via social media people more readily acquire “shared cognitions.” How do people come to share information? Who do they trust as a source of information? And who do they mistrust? Why would people adopt certain frames while

neglecting or paying less attention to others? We suggest that socially structured cognition is a new and inviting field in relation to collective action. Information search behavior has changed significantly, as have the available amount of information and the algorithms that “steer” the information to one’s screen. Take, for instance, the much-debated “alternative facts” and “fake news” in the 2016 and 2020 American presidential elections (see Jerit & Kam, Chapter 15, this volume). If social media have changed one thing profoundly, it is our perception of reality, in ways that fuel politicization, polarization and radicalization (e.g., Alberici & Milesi, 2015; Enjolras et al., 2014; Hong & Kim, 2016; Johnson et al., 2017; Lewandowsky et al., 2017).

Social media functions not only as an informational tool, but also as a tool of expression, the latter being, arguably, more important for protest participation. Providing an expressive mechanism, social media reduces the psychological distance between individual and collective action, as the cost increased from doing nothing to expressing something on social media is very low. Thus, future research could more thoroughly investigate how social media expression boosts levels of identification, positive incentives, and individual efficacy, and how they in turn lead to protest participation. Furthermore, the question remains how access to social media moderates the intentions not only to attend, but also actually to organize the protests. In other words, what are the long-term effects of social media on broadening the pool of collective action sympathizers?

Second, the discussion of social media raises another focal question: Does internet usage inspire offline political participation? What is the relationship between offline versus online participation? Some authors claim that increased online political discussion indirectly affects offline political participation through the influence of political information sharing (Lane et al., 2017). For instance, Greijdanus et al. (2020) conclude that social media facilitate online activism, particularly by collating individual experiences, community building, and the development of shared realities. They suggest that online and offline activism are positively related because social media posts can mobilize others for offline protest, although the visibility of activism could become risky in the repressive contexts.

On the other hand, future research could investigate whether online activism *hinders* offline protests. Virtual interaction in its essence is at odds with traditional models of predicting protest participation. These models assume that social movements are generated through direct participation in activities within an organizational context that explicitly expresses pro-societal stances and norms. Indeed, some studies show that online and offline civic participation have different attitudinal predictions, so these types of participation do not necessarily grow from each other. For instance, we have discussed studies in this chapter that show that social trust and civic responsibility lead to more (peaceful) collective action offline, while the same pattern is not found for online collective action (Oser, Hooghe & Marien, 2013; Machackova & Šerek, 2017). The fact that we observe two different patterns stems from the specific character of online participation, as it is typically performed at a relative distance from other people, rather than demanding direct personal interactions.

Virtual communication also has dubious effects on political efficacy as it provides only limited opportunities to feel a sense of accomplishment. Even if it enhances critical thinking and deliberation (Dahlgren, 2009), empirical data suggest that this kind of participation is not related to a desire to work towards common societal good (Machackova & Šerek, 2017). Thus, the concern remains that online participation may, in fact, boost greater acceptance

of radical attitudes and create a fragmented public sphere (Benkler et al., 2018; Klein & Muis, 2019). We could investigate the differences and similarities between people that participate online and offline (or both) to better understand whether traditional explanatory models of collective action adequately explain online participation, or whether we need to expand our models of collective action. For instance, the psychological inclination to participate offline and online could be investigated—do people restrict their actions to one domain? (c.f. Greijdanus et al., 2020). What are the goals of the activists and what are the mechanisms that convert online (dis)agreement to the actual protest in the streets? What are the potential dangers of online participation, to both participants on the individual level and political society as such?

Third, our chapter advocates for an integrated methodological framework that spans the disciplines of political psychology, sociology, political science, and communication science to enable a more holistic understanding of collective action. Future research could try to integrate different levels of development of collective action, by combining micro, meso, and macro perspectives. Combining different levels of analysis would provide a more comprehensive perspective on the origins of individual-level protest behavior. As Klandermans (2014) argues, we need an interdisciplinary approach to answer the following questions: What are key motives for action? To what extent do movement organizations appeal to these motives; and what are the opportunities and constraints imposed by a regime? Dynamics of demand represent factors at the micro level and are featured prominently in the political/social psychology literature (taking the individual as unit of analysis). The dynamics of supply and mobilization refer to the factors at the meso level and are mainly reflected in the discipline of sociology. The macro-level predictors—contextual dynamics—are most apparent in political science. Furthermore, we need more research on protest information, and how information leads to consensus, and how calls for action find their ways through current ecosystems of individuals, networks, and organizations. Thus, how information mediates action and is mediated relates to micro, meso, and macro levels of analysis and could be integrated in the findings of the disciplines mentioned. In sum, the field would benefit if scholars working in different disciplines talked more with each other, employing a cross-cutting approach to the dynamics of collective action (Christopher 2021).

Fourth, not only should different disciplines talk to each other, but so should scholars from different geographic regions. So far, social movement studies are predominantly Western-biased, except for a few notable exceptions (e.g., della Porta, 2015; Jacobsson & Saxonberg, 2016; Honari & Muis, 2021). The motivation to protest varies across contexts. There are differences in the dynamics of supply and demand. Context constrains perceived grievances, political efficacy, and the general motivation and willingness to protest. Some argue that social activism is constrained geographically (Piotrowski, 2015). Accordingly, theoretical and analytical approaches should be adjusted to take into account historical legacies, societal access to different levels of material, social and psychological resources, and the presence of a repressive regime. In the current context, pro-democracy protests and movements, such as those in Hong Kong and Eastern Europe, increase in scale and frequency across continents and countries, and are particularly worthy of our attention. Studying geographically diverse movements not only enhances scientific knowledge but also generates information that can help improve the world and enhance the future of democracy. Will these movements achieve meaningful political change and what role does

individual agency play in their success? Can politics from below bring humanity closer to a more equal and democratic world? And will social media facilitate these goals or conversely place greater stress on existing political and socio-economic cleavages? Answers to these questions will emerge in future years from the ever-expanding social movement society.

NOTE

Although the failed revolutions in Azerbaijan and Syria also reveal what happens when the right ingredients are not in place.

CHAPTER 27

PREJUDICE AND POLITICS

DONALD R. KINDER

My purpose in this chapter is to review the literature on the intersection between prejudice and politics. I confine my attention to research on prejudice and politics in the United States (a necessary restriction, because there is so much of it) and I concentrate on what we have learned about this subject since the previous edition of the *Handbook* (Kinder 2013)—quite a bit, in my estimation.

To discuss prejudice and politics in a serious way presupposes that we know both what race is and what prejudice is—and neither concept is straightforward. Accordingly, the first two sections of the chapter spell out the meaning of these two central ideas: first “race” and then “prejudice.” The next section acknowledges that, in practice, prejudice is understood in different ways and expressed in different forms. With this in mind, I review what we have learned recently about the decline of biological racism, the meaning and measurement of modern racism, and the growing interest in the political relevance of implicit racism. The next section, and the heart of the chapter, summarizes evidence on the part played by prejudice in shaping the political lives of Americans on consequential matters. The final section considers, in light of recent events in the United States (and elsewhere in the developed world), the prospects for democracy in a society divided by race.

1. THE IDEA OF RACE

Throughout the 19th century, biologists employed the term “race” to refer to fundamentally different kinds, and their empirical research was devoted to establishing a racial hierarchy, with white people (“Caucasian”) at the top and black people (“African” or “Ethiopian”) at the bottom.¹ Well into the 20th century, race retained respectability and widespread use as a scientific category. Differences between races—assumed to be inherent and immutable—continued to be regarded as established matters of fact, and “the inferiority of certain races was no more to be contested than the law of gravity to be regarded as immoral” (Barkan 1992, p. 3).

We now know was a mistake. Genetic diversity in human groups is overwhelmingly a matter of individual variation within populations. History in the long run is a recurrent story

of migration and conquest, of the relentless intermingling of human groups. Americans classified as black have variable amounts of European ancestry, and many Americans classified as white have some African ancestry. The notion that all of human diversity can be reduced to a small number of distinct races, once taken for granted in the scientific community, has been abandoned (Lewontin 1995; Futuyma 2005).

That race has largely disappeared from biology is important, but it does not settle anything for us here. Our interest is in race as understood by everyday people, and in this sense, race is very much alive. Most of us rarely think twice about assigning people we meet to racial categories; indeed, this is such an automatic habit, it could be said that we do not think about classifying people by race at all (e.g., Bruner 1957; Fazio and Dunton 1997).

Seen this way, racial categories are psychological entities. They are concepts: “mental representations of a world outside the mind” (Gelman 2019, p. 314). Concepts are indispensable; without them, mental life would be chaotic, language would be staggeringly complex, and communication virtually impossible (Smith and Medin 1981). “Life is so short,” Gordon Allport once wrote, “and the demands upon us for practical adjustments so great, that we cannot let our ignorance detain us in our daily transactions. We have to decide whether objects are good or bad by classes. We cannot weigh each object in the world by itself. Rough and ready rubrics, however coarse and broad, have to suffice” (1954, p. 9).

Racial categories are understood to be “natural kinds” (Rothbart and Taylor 1992). Unlike human artifacts, natural kinds are taken to be part of the biological world (Gelman 2003, 2019; Hirschfeld 1996). Members of natural kind concepts share not only observable features but also a deeper reality; that there exists an inherent, immutable substance or property—blood, genes, some mystical force—that generates the characteristics that members share. The understanding of racial groups as natural kinds emerges early in life. By the time American children enter elementary school, they believe that racial groups exist, that persons belong to such groups on the basis of observable characteristics, that race is transmitted and fixed at birth, and that differences between races arise from something basic and fundamental (Hirschfeld 1996).

Whatever biological science says, race remains real in American life. Real and consequential: race is inscribed in American law, entrenched in social experience, imprinted on economic life, and, as we will soon see, influential, still today, in our politics.²

2. THE NATURE OF PREJUDICE

Prejudice—or racism (I will use the two terms interchangeably)—is a species of attitude. And by attitude, I mean, following Gordon Allport, a “mental and neural state of readiness” (Allport 1935, p. 810). Attitudes represent “a tendency to act in favor of, opposed to, in behalf of, or in contradiction to, the object with which it is related” (Allport 1935, p. 837). Attitudes are predispositional and, as such, fundamental to the human enterprise, both in the immediate present and in the evolutionary past (e.g., Kahneman 2003; Zajonc 1980).³

In the United States, race prejudice represents a tendency on the part of white Americans to act in opposition to the interests and aspirations of black Americans.⁴ The core of prejudice is enmity, expressed through both negative emotions and denigrating beliefs (Fredrickson 2002; Pettigrew 1982; Wilson 1973). Prejudice is categorical, in that racial groups in general,

and “blacks” in particular, are understood to be natural kinds. Prejudice takes natural kinds for granted: that human populations can be partitioned into distinct types on the basis of their physical differences. Prejudice is also dimensional, in that prejudice varies continuously from one person to the next. For some white Americans, race is a largely incidental and inconsequential feature of social life. For others, like active members of the Ku Klux Klan, race is the main thing. Most fall somewhere in between these extremes. It would be a mistake to assume that people either are racist, or they are not. Prejudice is a quantity, not a kind.

There are as many attitudes as there are objects in the world. We are interested in prejudice in particular because of its connection to inequality, discrimination, and segregation. Prejudice, as Herbert Blumer reminds us, “reflects, justifies, and promotes the social exclusion of the subordinate racial group” (1958, p. 4; Wilson 1973).

Blumer’s point raises an important question. Does prejudice *necessarily* include opposition to policies and practices designed to reduce discrimination and to advance the interests and aspirations of black Americans? I do not think so. Voting against a black candidate, or opposing affirmative action, cannot by itself be taken as evidence of prejudice. The heart of this chapter is devoted to assessing the extent to which prejudice motivates the choices white Americans make about parties, candidates, and policies. I take this is to be an empirical question, not something to be settled by definition. For the purpose of this essay, it is perhaps *the* empirical question.

3. VARIETIES OF PREJUDICE

As a practical matter, prejudice—or racism—is not one thing. Prejudice (racism) comes in more than a single variety. In the previous edition of this chapter (Kinder 2013), I suggested that it was useful to classify types of racism according to three sets of binary distinctions: biological (old-fashioned) versus cultural (modern), cognitive (stereotype) versus affective (visceral), and implicit (unconscious) versus explicit (conscious). Combinations of these features capture differences in how prejudice is conceived and assessed. In this section of the chapter, guided by these distinctions, I take up the apparent decline of biological racism; the continuing discussion over the meaning and measurement of modern racism; and the growing interest in the political consequences of implicit racism.

3.1. Decline of Biological Racism

By the latter stages of the 17th century, slavery was established throughout the Southern colonies. At the time of the first US Census in 1790, African Americans—nearly all enslaved—made up roughly 20% of the national population and more than one-third of the population of the South (Farley and Allen 1987).

Slavery was justified on the ground that the African was fit for slavery and for slavery alone. That was racist, but it was not until slavery came under direct attack by the abolitionists in the early decades of the 19th century that the presumption of black inferiority developed into a full-blown theory. Prior to the abolitionist challenge, slaveholders defended their

practice—insofar as they were called upon to do so—merely by referring to the fact that slavery was a legally sanctioned economic arrangement. They did not need to make the argument that blacks were inferior; that was simply taken for granted.

In the early decades of the 19th century, however, slavery began to be debated. Northern abolitionists argued that slaveholding was evil. Southern slavers, intellectuals, and statesmen rose—if that is the right way to put it—to the challenge. The debate over slavery eventually transformed what had been a mostly unthinking assumption of racial superiority into a self-conscious theory of racism, “a rationalized ideology grounded in what were thought to be the facts of nature” (Fredrickson 1971, p. 2).

And what were these so-called facts of nature? The Negro and the white comprised separate and fundamentally distinct races. Differences between them in intellectual capacity and moral character were obvious, inborn, and permanent. Sexual liaisons between black men and white women were an abomination. A racially integrated society was impossible; more than that, it was unimaginable.

The Civil War brought an end to slavery, but other forms of racial oppression survived, and still more were invented. After Reconstruction, African Americans were excluded from politics, ostracized from social life, and confined to the meanest work. For all of this, biological racism, as I will call it, provided justification and, insofar as it was needed, moral consolation. This form of race prejudice persisted well into the 20th century—endorsed not just by ordinary citizens (as far as we can tell), but by scientists, intellectuals, church leaders, and statesmen alike (Fredrickson 1971; Myrdal 1944).

This is no longer the case. Elite expressions of biological racism are today much harder to find in books, journals, sermons and speeches (Myrdal 1944; Kinder and Sanders 1996), and perhaps at least partly for this reason, biological racism is much harder to find in the American public. From World War II to the present, biological racism has undergone slow, gradual, and steady erosion. Support for the idea that black Americans suffer inborn and immutable inferiority has not disappeared, but it has substantially diminished. The notion of biological impairment, of permanent disadvantage, is much less prominent now than it once was (Apostle et al. 1983; Kinder 2023; Kinder and Chudy 2016; Schuman, Steeh, Bobo, and Krysan 1997).

It turns out that decline in white support for biological prejudice is due preponderantly to generational replacement. Elderly cohorts of whites, in possession of old-fashioned beliefs about race, have been gradually replaced by younger (and better-educated) cohorts, more likely than their elders to reject the claim of innate, biological, categorical superiority (Kinder and Chudy 2016; Kinder 2023). Generational replacement has sometimes been referred to as “social progress through death.” The decline in white support for biological racism appears to be an excellent case in point.⁵

3.2. Meaning and Measurement of Modern Racism

Even if biological racism were to disappear entirely, it would not mean the end of racism. Much as biological racism emerged in fully articulated form out of the debate over slavery, a new, modern variety of racism arose out of the racial crisis of the 20th century. Or so it is argued. The new racism travels under various names: “symbolic racism” (Sears and Kinder 1971; Kinder and Sears 1981; Sears 1988), “modern racism” (McConahay 1986), “racial

resentment” (Kinder and Sanders 1996), and “laissez faire racism” (Bobo and Smith 1998). There are differences among these, but all share the view that biological racism has largely faded away, and that a new form of racism (“modern racism,” I’m going to call it here) has largely taken its place.

The two forms of racism are alike in several important respects. Both emerged out of a national crisis. Both offer an account of racial differences in wealth, status, and power that is flattering to whites and denigrating to blacks. Both provide justification for exclusion and neglect—but they do so in different ways. Biological racism understands differences between blacks and whites to be profound and unalterable, rooted in nature. On the account offered by the new racism, racial inferiority is more cultural than biological, seen in the customs and folkways of black life: idleness, violence, drug abuse, abandoned children—the whole “tangle of pathology” that many whites see as characteristic of life in black families and neighborhoods.

Modern racism has come to occupy a prominent position in scholarship on race and American politics—prominent, but not unchallenged. In their chapter in the 2009 *Annual Review of Political Science*, Leonie Huddy and Stanley Feldman conclude: “To a very considerable extent, the debate over the continued political effects of racial prejudice hinges on an ongoing dispute over the nature and measurement of racial prejudice” (p. 425). By this they are referring to the ongoing and, in their judgment, unresolved dispute over the nature and measurement of modern racism in particular.

It is fair to say that this discussion is still ongoing—as it should be. Social science is bristling with disagreements over what things mean and how they should be measured. Such disagreements are perhaps inevitable, given the complexity of concepts, the imprecision of language, and the technical vexations of assessment. It should not surprise us that the new racism thesis has given rise to spirited and energetic debate.

One important line of criticism contends that modern racism, as typically measured, is not racism at all. Standard measures of modern racism get at something else: white Americans’ commitment to individualism (Sniderman and Hagen 1985), or their intuitive sense of justice (Sniderman and Carmines 1997), or their embrace of conservatism (Acharya, Blackwell, and Sen 2018; Feldman and Huddy 2005), or their ignorance of history (Huddy and Feldman 2009).⁶

A second critique begins by acknowledging that modern racism has played a significant role in American politics in the past, but that its importance is waning. Christopher DeSante and Candis Watts Smith (2020) point out that the events that gave rise to the new racism are fading into history. They suggest that recent events have given rise to a new form of racism (post-modern racism?), centering on the denial of systemic racism.

Other work in this line is more technical. Are standard measures of modern racism equivalent across groups (DeSante and Smith 2020; Pietryka in press)? Is modern racism one thing or two (Tarman and Sears 2005)? How could standard measures be improved (Wilson and Davis 2011)? Which indicators should be replaced (Huddy, Feldman, and Pen in press)? What is being measured when standard measures of racism are asked of African Americans (Kam and Burge 2018; Tesler and Sears 2010)? Work of this kind is exactly what one hopes to see in a discipline with scientific aspirations.

A final point worth noting here concerns trajectory. As we saw in the preceding section, biological racism appears to be on a long, steady decline. The story for modern racism is different. Over the past half century, modern racism is essentially stationary: no evidence of

progress, but no evidence of retrogression, either (Kinder and Chudy 2016). Until the spring of 2016, that is, when modern racism suddenly and significantly declines. This change seems to be real: it shows up on all measures, across several surveys, and in interviews carried out in person and over the internet. The change is substantial among Democrats and it is negligible among Republicans (Hopkins and Washington 2020; Hout and Maggio 2021; Kinder 2023). What is responsible for this change? Is the decline in racism temporary or the beginning of a trend? Good questions.

3.3. Political Relevance of Implicit Racism

In a society overrun by polls and surveys, it is easy to take for granted that attitudes are measurable. We might disagree over the best method for doing so but not over the possibility of the enterprise itself. It was not always so. In the early decades of the 20th century, psychology was dominated by behaviorism. The idea that aspects of mentality could be assessed, or even that it was desirable to try, ran against convention. In 1928, the experimental psychologist L. L. Thurstone announced, to a skeptical audience, his discovery that attitudes could be measured (Thurstone 1928). His pioneering venture was followed in short order by projects led by Likert, Guttman, Coombs, Osgood, and others. These “measurement men,” as Banaji and Heiphetz (2010) called them, “achieved the previously unthinkable; for the first time ever, they took the ephemeral mental quality of *favoring* and *disfavoring* and rendered it the subject of scientific study” (p. 349). The rest, as they say, is history. Attitude became the “keystone in the edifice of American social psychology” (Allport 1935, p. 798).

The methods developed by Thurstone and his colleagues varied in important ways, but all shared one feature in common: each relied on introspection. In one way or another, people were asked to reflect on some subject (immigration, say, or the New Deal), to retrieve their thoughts and feelings relevant to the subject, and then to report what it was that they thought and felt. Attitudes were measured directly. For nearly one hundred years, attitudes, including prejudice, have been assessed overwhelmingly in this fashion.

Meanwhile, in recent decades, psychology has been generating experimental results demonstrating that not all attitudes are accessible to introspection. Implicit attitudes, as they are called, evade the conscious mind; they are “introspectively unidentified (or inaccurately identified) traces of past experience” (Greenwald and Banaji 1995, p. 8). Implicit attitudes are activated automatically and influence judgment and behavior outside awareness (Greenwald, McGhee, and Schwartz 1998; Gawronski and Payne 2010).

Implicit attitudes require new and subtle methods of measurement. Most rely on experimental procedures adapted from cognitive psychology (Gawronski, De Houwer, and Sherman 2020; Wittenbrink and Schwarz 2007). Such methods would seem to offer a way to get at those attitudes—like prejudice—that people might not care to acknowledge even to themselves. What have we learned about prejudice, conceived of as an implicit attitude?

First of all, implicit prejudice can be measured reliably (e.g., Greenwald and Banaji 1995). Second, racial bias in implicit form is extremely robust. Implicit prejudice against black Americans shows up in study after study, and not only among white Americans, but also among Asian, Latino, and Native Americans. Only African Americans come off as free of racial bias (Gawronski and Bodenhausen 2006; Nosek et al. 2007). And third, although

implicit and explicit measures of prejudice are positively correlated with each other, the correlations run small: implicit and explicit prejudice are far from interchangeable (Greenwald et al. 2009; Kinder and Ryan 2017).

This last result is important, in that it suggests that implicit and explicit measures of prejudice could have separate and distinct consequences for politics. The evidence bearing on this possibility is thin and mixed. A number of well-conceived studies show that implicit attitudes influence the decisions people make in politics, over and above the effects due to explicit attitudes (e.g., Mo 2015; Iyengar and Westwood 2015; Ryan 2017; Perez 2016). None of these studies concerns racial prejudice, however. And research that does take up prejudice generally finds that once direct measures of explicit prejudice are taken into account, implicit prejudice has no independent effect (Ditonto, Lau, and Sears 2013; Kalmoe and Piston 2013; Kinder and Ryan 2017; Pasek et al. 2009; Payne et al. 2010).⁷

At this relatively early stage, it would be premature, to put it mildly, to conclude that the effect of racial prejudice on the decisions citizens make in the domain of politics is confined to explicit prejudice. More evidence is surely needed. And even if further studies continued to return negligible results, it would be a mistake to write off implicit prejudice altogether. The psychology literature is running over with demonstrations showing that implicit prejudice predicts judgment and action in many consequential social settings (e.g., Greenwald et al. 2009; Green et al. 2007; Gawronski and Payne 2010; Greenwald and Banaji 2017).⁸

4. POLITICAL CONSEQUENCES OF PREJUDICE

To what extent and under what conditions does prejudice spill into politics? In this section of the chapter, I review evidence on the part played by prejudice in shaping the political lives of Americans in three important ways: the political party they identify with, the candidates they support, and the policies they favor. This research relies primarily on one measure or another of modern racism. My review assumes that such measures are imperfect but serviceable, adequate to the task at hand. Readers who think, to the contrary, that current measures are deeply and irretrievably flawed can stop reading at this point (actually, all of you are free to stop whenever you like).

In trying to bring order to this literature, I have found two ideas especially useful: “priming” and “racialization.” Priming refers to the idea that judgment depends in part on what comes immediately to mind at the moment judgment is rendered—on considerations that are, for whatever reason and however briefly, accessible (Tversky and Kahneman 1974). Priming is implicated in politics (Iyengar and Kinder 1987). In their role as citizens, Americans are called upon to make judgments of various alternatives: they decide whether to support or reject candidates for public office, they find policy proposals wise or terrible, they conclude that a political party is for them or not, they take the results of government action to be successful or disastrous, they judge the president’s performance to be inspiring or deplorable, and so on. These various alternatives are always complex, and such complexity makes it difficult to know what standards should be applied in any single case. The intuition behind priming is that these standards are supplied or at least encouraged by the preoccupations of mass communications. How political alternatives are judged depends in part on which stories media choose to cover, and, consequently, which standards are made

salient. The more attention media pay to a particular aspect of political life—the more frequently that aspect is *primed*—the more citizens will incorporate what they know and feel about it into their political judgments. Defined this way, priming has received strong and consistent support, in both experimental and observational studies (for a review, see Kinder 1998), and I will make use of it here.

The complement to priming is racialization. Priming is a psychological mechanism. Racialization refers to the external environment of politics—more specifically, to how parties and candidates and policies are framed. Parties, candidates, and policies are racialized insofar as they are framed in such a way as to encourage citizens to understand them as having racial implications. Together, priming and racialization provide a measure of how far race has become insinuated into politics.

The literature I am about to review includes laboratory, field, and natural experiments. But to a large extent, the conclusions I draw rest primarily on correlations. Well, there are correlations and then there are correlations. The evidence I rely on comes from strong designs and careful analysis. Alternative explanations—based in partisanship, political principles, ideological identification, white identity (Jardina 2019), racial sympathy (Chudy 2021), and more—are taken into account. To be reported here, the estimated effects of prejudice must be substantial (not merely statistically significant) and must stand up across multiple tests.

4.1. Prejudice and Partisanship

At the center of politics in the United States are the political parties, enduring coalitions among politicians, interest groups, activists, and donors. Parties nominate candidates, wage campaigns, set agendas, propose policies, and pass legislation. One might say—E. E. Schattschneider has said it—that modern democratic government is “unthinkable save in terms of parties” (1942, p. 1).

Just as political parties are indispensable to the work of politics, partisanship is indispensable, or nearly so, to the political work of citizens (e.g., Bartels 2000; Campbell, Converse, Miller, and Stokes 1960; Green, Palmquist, and Schickler 2002; Huddy et al. 2015), and is implicated in what I take to be the two most important developments in American politics since World War II: realignment, the sharp reversal of party fortunes in the American South beginning in the 1960s; and polarization, the growing distemper in recent decades between Democrats and Republicans in the nation as a whole. These two developments turn out to be connected, and both, as we are about to see, are connected to prejudice.

4.1.1. *Realignment*

From the end of Reconstruction to the New Deal, no section of the country was more solidly Democratic than the South. As late as 1950, Southern whites were some 40 percentage points more likely to be Democrats than were whites living outside the South. Today, the South is decisively Republican (Black and Black 2013; Lublin 2021).

Several explanations have been offered for this staggering change. According to Shafer and Johnston (2006), the “engine of partisan change in the postwar South was, first and

foremost, economic development” (p. 94). Similar in spirit, McCarty, Poole, and Rosenthal (2016) argue that as Southern whites got richer, they naturally (in the economist’s telling) moved away from the party of redistribution. A second line of argument proposes that white Southerners were drawn to the Republican Party primarily by the promise of lower taxes, limited government, reduced regulation, and restored patriotism—and not by the Democratic Party’s backing of civil rights initiatives (Black and Black 1987). Lynn Sanders and I (Kinder and Sanders 1996) argued to the contrary, that the precipitating event for partisan change in the South was the sudden shift in the position of party elites on civil rights, made dramatically visible in the 1964 presidential election (Carmines and Stimson 1989; Valentino and Sears 2005).

In the previous installment of this chapter, I concluded that the evidence available at the time was insufficient to adjudicate decisively among the alternative explanations. This is no longer so. Ilyana Kuziemko and Ebonya Washington (2018) provide a convincing analysis of the movement of Southern whites out of the Democratic Party. Kuziemko and Washington establish two key points. First, the decline of the Democratic South began in the spring of 1963, as President Kennedy engaged in a series of high-profile confrontations with Governor Wallace over desegregation of the University of Alabama. This moment marked the beginning of an historic reversal: the Democratic Party, the party of white supremacy, was becoming the party of racial liberalism; the Republican Party, the party of Lincoln and emancipation, was becoming the party of racial conservatism (Carmines and Stimson 1989).⁹ And second, the decline in Democratic partisanship took place almost entirely among white Southerners who reported they would not vote for a qualified presidential candidate from their own party who happened to be black. Kuziemko and Washington conclude that “defection among racially conservative whites just after the Democrats introduce sweeping Civil Rights legislation explains virtually all of the losses in the region” (p. 2865). The realignment of party and power in the American South was driven not by economic interests, nor by conservative principles, but by racialization.

4.1.2. *Polarization*

Animosity between partisans is rising. For thirty years and perhaps longer, Democrats have been expressing increasing hostility toward Republicans. Over the same period, Republicans have been returning the favor, expressing increasing hostility toward Democrats. Republicans and Democrats also disagree more sharply with each other than they used to—over domestic policy, international affairs, presidential performance, and more (Brown and Enos 2021; Iyengar, Lelkes, Levendusky and Malhotra 2019; Levendusky 2009). Polarization threatens social cohesion, impairs communication, increases enmity, and can turn ordinary disagreements into implacable conflicts (Coser 1956).

Does prejudice have a part to play in polarization? Probably, though the evidence is circumstantial. As Southern whites began moving out of the Democratic Party in the 1960s, blacks were moving in. Thanks to Supreme Court decisions, voter registration drives, and the 1965 Voting Rights Act, blacks in the South (where most lived) began to vote in large numbers, and when they did, they voted overwhelmingly for Democrats. Today, the racial divide in partisanship is enormous. In 2016, 81% of blacks identified as Democrats, compared to just 38% of whites.¹⁰

The racial divide is even greater than these percentages imply. This is because among white Americans, the association between partisanship and prejudice has increased sharply over the last several decades. Thirty years ago, Democrats and Republicans were indistinguishable from one another on measures of modern racism. Today, they differ markedly. This sorting appears to be due at least in part to white Americans bringing their partisanship into conformity with their views on race (Engelhardt 2019, 2021; Kinder and Chudy 2016; Tesler 2016).

In three experiments, Westwood and Peterson (2022) show how close the connection between race and partisanship has become. They find that treatments that induce mildly unpleasant experiences between blacks and whites lead to increased animosity toward members of the opposite party. The reverse holds as well: treatments that induce mildly unpleasant experiences between Democrats and Republicans lead to increased animosity toward members of the opposite race. Westwood and Peterson conclude that in American politics today, race and partisanship are “enmeshed.”

4.2. Prejudice and the Vote

Prejudice, as we have seen, has become part of partisanship. Insofar as partisanship influences voting, then prejudice also influences the vote. My interest in this section goes beyond the indirect role of prejudice on voting. Here I wish to convey what we know about the impact of prejudice on the vote over and above the effects due to partisanship or ideology or principles or economic interests—prejudice as an independent electoral force.

At the outset, I presume that prejudice will be more or less potent in this role depending on the prominence and clarity of cues signaling that the candidates differ substantially in the racial groups they favor and oppose. The magnitude of the difference, the clarity of the difference, and the prominence of the difference: together, these three constitute the preconditions for racialization. In the presence of these conditions, voters will be more likely to be asking themselves: is this candidate *for us*, or is this candidate *for them*, where “us” and “them” are defined in racial terms.

A notable case in point is provided by Barack Obama’s run for the presidency in 2008. Apart from partisanship, nothing predicted the 2008 vote more effectively than prejudice (Kinder and Dale-Riddle 2011; Lewis-Beck, Tien, and Nadeau 2010; Pasek et al. 2009; Payne et al. 2010; Piston 2010; Stephens-Davidowitz 2014; Tesler and Sears 2010). Racially resentful whites voted against Obama more than they otherwise would have had Obama been white; racially sympathetic whites voted for Obama more than they otherwise would. On balance, Obama lost more votes among whites than he gained. If prejudice as a short-term force could somehow have been erased in 2008, Obama would have won in a landslide (Kinder and Dale-Riddle 2011; Lewis-Beck, Tien, and Nadeau 2010; Stephens-Davidowitz 2014).¹¹

That Obama won is evidence that blackness is no longer automatically and categorically disqualifying for the highest office in the land—a welcome if long-delayed achievement. Obama won, but did so in spite of his race. He won because conditions could hardly have been worse for the opposition: the ongoing and dispiriting war in Iraq, the collapse of financial institutions, the beginnings of a terrifying recession, all presided over by an increasingly unpopular Republican president. In the absence of all the terrible news, it is unlikely

that Obama would have won at all (Kinder and Dale-Riddle 2011; Lewis-Beck, Tien, and Nadeau 2010).

Obama ran again in 2012, and as we all know, he won again. After a full term of Obama as president, was race receding from politics? One reason to think this could be so arises from the shortfall between Obama's performance as president and what white Americans might have expected of him before he assumed office. Zoltan Hajnal (2006) argues that when a black person runs for mayor for the first time, whites fear the worst. What actually transpires is much less than whites fear. Once in power, black mayors do not turn the tables, pursuing policies that punish whites. As a consequence, when black mayors stand for re-election, whites are less agitated; their fears are diminished; their attitudes toward blacks improved. Unhappily, this does not seem to apply to Obama. Prejudice appears to have been just as present and just as important in Obama's re-election as it was four years before (Kinder and Chudy 2016; Petrow et al. 2018; Stephens-Davidowitz 2014; Tesler 2016). Obama, evidently, was still black.

Obama was racialized, and so, it appears, were other aspects of politics during his presidency. Prior to Obama's election, prejudice had little to do with Congressional voting.¹² In the 2010, 2012, and 2014 House elections, however, prejudice played a significant role (Tesler 2016). Another example concerns the Tea Party, a politically significant movement which arose shortly after Obama's inauguration, ostensibly as a protest against big government, burdensome taxes, and budget deficits. It was partly that, but it was also a reaction against the idea of a black man moving into the White House (Parker and Barreto 2014; Skocpol and Williamson 2016; Tesler 2016).

Obama's influence seems to extend even to the construction of reality. Politics is a complicated business, and it takes place, for the most part, far away. The average person pays attention intermittently and casually. Under these circumstances, many citizens may feel free to construct a picture of the political world that reinforces their predispositions—in effect, and to a degree, to make up their own facts. So it seems when it comes to America's first black president. Where was Obama born? What religion does he practice? Is his skin light or dark? Is his economy improving or deteriorating? Are his policies on race more or less generous to black Americans than those advanced by Democratic presidents before him? These questions ask not for preferences but for, to use an old-fashioned term, the truth. Nevertheless, the answers white Americans provided to all these questions were significantly and substantially shaped by their attitudes on race (Hutchings, Cruz, Gause, and Piston 2021; Jardina and Traugott 2019; Kemmelmeier and Chavez 2014; Tesler 2016).

The far-reaching racialization of politics during the Obama administration led Valentino, Neuner, and Vandebroek (2018) to declare the end of racial priming. Prior to Obama's appearance on the national stage, it seemed easy enough to demonstrate priming effects through subtle racialization treatments (e.g., Hurwitz and Peffley 2005; Iyengar and Kinder 1987; Mendelberg 2001; Valentino, Hutchings and Whites 2002). Afterward, not so. Valentino and his colleagues (2018) argued that the Obama presidency made race and prejudice chronically accessible, and as a consequence, experimental treatments highlighting race that once primed prejudice no longer did so.

Obama may be a special case (all cases are of course special in some aspect), but like Obama, black candidates running for office are generally penalized for their race. Substantial racial bias shows up in Senate and gubernatorial races (Tokeshi 2020), in House elections (e.g., Lublin 2021), in voting for delegates in presidential primary contests (Broockman and

Soltas 2020), and in school board elections (Flavin and Hartney 2017). Black candidates are damaged more than their white counterparts by allegations of sexual impropriety (Berinsky et al. 2011), they are damaged more than white candidates by taking ambiguous positions on policy (Piston, Krupnikov, Ryan, and Milita 2018), and they face serious obstacles when trying to counter racist appeals by their opponents (Banks and Hicks 2019). The race penalty and its complexities are investigated in a continuing series of experiments that manipulate the racial identity of fictitious candidates (e.g., Kirkland and Coppock 2018; Kripnikov et al. 2016), and in a new series of experiments that manipulate candidate skin color, finding that whites are inclined to favor black candidates with lighter complexions (Messing et al. 2016; Weaver 2012).¹³

A candidate's racial identity and color are just two of many possible cues signaling alignment or opposition to racial groups. Others include taking positions on policy, drawing attention to problems while ignoring others, associating with certain kinds of people, and more. This implies black candidates can be rewarded by racially conservative whites and punished by racially liberal whites insofar as they are seen to stand against the interests of "their people" (Hood and McKee 2015; Karpowitz et al. 2021; LaFleur Stephens-Dougan 2021). The same applies to white candidates, who can choose to make race more or less central to their campaigns (Kinder and Sanders 1996).

This last point brings us to Donald Trump. It is not hard to show that, among other things, the Trump's successful campaign for the presidency was appealing to racism (e.g., Smith and King 2021). But it is a separate matter to establish that voters were responding on this ground. Trump was selling racism: were voters buying it? The evidence is abundant that they were. Racism was as important to the white vote in 2016 as it was in the Obama elections, if not more so (Green and McElwee 2019; Hopkins 2021; Jardina 2020; Reny et al. 2019; Schaffner, MacWilliams, and Nteta 2017; Sides, Tesler, and Vavreck 2018; Smith and Hanley 2018).¹⁴

Trump's success is troubling on another front. In her award-winning book, Tali Mendelberg (2001) argued that in the aftermath of the civil rights movement, candidates and parties could no longer rely on explicitly racist appeals. In a political system that frowned upon racist speech, such appeals would backfire. Appeals to prejudice continued, but to be effective, they had to be careful, subtle, euphemistic.

This is not the campaign that Donald Trump presented to the American public. Here's what the Trump campaign looked like to Robert Kagan, writing in the *Washington Post* in May of 2016: "What he [Trump] offers is an attitude, an aura of crude strength and machismo, a boasting of disrespect for the niceties of the democratic culture that he claims, and his followers believe, has produced national weakness and incompetence. His incoherent and contradictory utterances have one thing in common: They provoke and play upon feelings of resentment and disdain, intermingled with bits of fear, hatred, and anger. His public discourse consists of attacking or ridiculing a wide range of 'others'—Muslims, Hispanics, women, Chinese, Mexicans, Europeans, Arabs, immigrants, refugees—whom he depicts either as threats or as objects of derision. His program, such as it is, consists chiefly of promises to get tough with foreigners and people of nonwhite complexion. He will deport them, bar them, get them to knuckle under, make them pay up or make them shut up."¹⁵

Careful? Subtle? Euphemistic? Not in the least. And yet, Trump's campaign certainly seemed to be effective. He was nominated over a host of more qualified candidates, he was

elected president in 2016, and despite a severe recession and a murderous pandemic on his watch, Trump was very nearly re-elected in 2020. It is not at all clear that delicacy is required for prejudice to be primed (Huber and Lapinsky 2006, 2008; Hutchings, Walton and Benjamin 2010; Mendelberg 2008a, 2008b; Stephens-Dougan 2016).

A final point: the prominence of prejudice in voting is not just a matter of who the candidates are and how they present themselves. It depends also on voters' surroundings. In *Southern Politics*, V. O. Key (1949) showed in meticulous detail that politics in the South through the first half of the 20th century was most reactionary in the so-called Black Belt: an arc that ran from the Chesapeake Bay in the northeast, through the eastern shore of the Carolinas, round the midlands of Georgia and Alabama, along the rivers of Mississippi, Arkansas, and Louisiana, and into east Texas. It was within the Black Belt where slavery had flourished, where African Americans in large numbers still lived, and where, as Key put it, whites possessed "the deepest and most immediate concern with the maintenance of white supremacy" (p. 5).

Key's observations have been corroborated in scores of subsequent studies, recently and most notably by Ryan Enos (2016, 2017). In an ingenious design, Enos made good social science use of the city of Chicago's decision to demolish large public housing projects. The projects amounted to high-rise ghettos, populated overwhelmingly by black Chicagoans. From the point of view of whites, they were, as Enos put it, "places where the other lived, places where white people didn't go—a hulking mass of the outgroup, visible from across the freeway" (2017, p. 146). Enos found, consistent with the racial threat hypothesis, that after the projects were demolished, white Chicagoans living close to project sites were less likely to vote and, when they did vote, were less likely to support racially conservative candidates.¹⁶

4.3. Prejudice and Opinion on Policy

Democracy means government responsive to its people. In a true democracy, what the people want—on immigration or Social Security or affirmative action—shapes what the government actually does. This is the way things are supposed to work. Insofar as they actually do work this way, opinion on policy becomes, as James Stimson once put it, the "drive wheel" of politics.¹⁷

This sounds good, and it is good, as far as it goes. But often overlooked in this simple view of representation is the degree to which opinion on policy arises from anti-democratic sentiments. If the public gets what it wants, but what it wants is shaped by racism, then the representation of public opinion in policy works against the democratic project. With this in mind, in this section of the chapter, I review evidence on the relationship between prejudice and opinion on policy.

It should come as no surprise, this far in, to learn that the effect of prejudice on opinion is pronounced on policies where the racial consequences are explicit, where racialization is built in. On fair housing, school desegregation, affirmative action in college admissions, and more, prejudice plays a major role (e.g., Sears, Sidanius, and Bobo 2000). More interesting, and more troubling, is that prejudice also has effects on opinion on issues where race is present only by implication.

One well-researched example is welfare. Welfare programs such as Food Stamps are unpopular among white Americans, and they are especially unpopular among whites who

score high on standard measures of prejudice. This finding is robust, across time and context, models, experimental and observational studies, different measures of racial attitudes, and with stringent controls on alternative explanations (e.g., DeSante 2013; Gilens 1999; Mendelberg 2001; Kinder and Sanders 1996; Kinder 2023; Valentino, Hutchings, and White 2002; Winter 2006).

Why does prejudice figure so prominently in how white Americans think about welfare policy? Let us count the ways. Media overrepresent blacks among the poor. Racially stereotyped representations of welfare recipients are common. Elite discussions of welfare policy traffic routinely in racial code. On top of all this, there is the close fit between the racialized language surrounding debates over welfare reform, on the one hand, and central themes of modern racism, emphasizing self-reliance and discipline, on the other (Gilens 1999; Quadagno 1994; Patterson 2000).

Another clear case of racialization is provided by policy in the domain of crime. By a substantial margin, the United States imprisons a larger fraction of its population than any other country in the world. Mass incarceration falls disproportionately on African Americans. Blacks are more likely than whites to be arrested and much more likely to be imprisoned (Travis, Western, and Redburn 2014). In media coverage of crime, black perpetrators are over-represented and portrayed in stereotyped ways (e.g., Entman and Rojecki 2010; Gilliam, Iyengar, Simon, and Wright 1996; Gilliam and Iyengar 2000). White Americans associate crime with blacks (Schaller et al. 2003), and blacks with crime and danger (Payne 2001).

It is no surprise, then, that the effects of prejudice on policy within the domain of crime and punishment are pervasive. Building prisons, abolishing furlough programs, executing convicted murderers, siding with police, defending the right to bear arms: on all these subjects, prejudice plays an important role (Carter and Corra 2016; Filindra and Kaplan 2016; Filindra, Kaplan, and Buyuker 2021; Hurwitz and Peffley 2005; Peffley and Hurwitz 2002, 2010; Strickler and Lawson 2022).

The dramatic rise in incarceration in the United States since 1970 seems to have followed public demand. Americans wanted a more punitive criminal justice system—and they got it (Enns 2014). From one point of view, mass incarceration is a democratic result, a fine example of giving the public what it wanted. What the public wanted and why it wanted what it did, is another matter.

A third case of racialization returns us to the Obama presidency. During the 2008 presidential campaign, Obama promised to fix the American health care system if he were elected. In March of 2010, Congress passed and the president signed the Patient Protection and Affordable Care Act (ACA). The policy extended coverage to some 30 million uninsured Americans, reorganized and expanded Medicaid for the poor, imposed stricter regulation on private health care insurance, and created new insurance purchasing organizations (“exchanges”) in an effort to curtail rising costs.

The ACA became law, but only after overcoming ferocious opposition. As the vote approached, thousands of protestors descended on the Capitol. Congressman John Lewis, making his way through the Longworth House office building, was singled out for abuse. Some in the crowd screamed “nigger.” Others spat upon his companion, Representative Emanuel Cleaver, a Democrat from Missouri and, more to the point, African American. In the meantime, Rush Limbaugh, the king of talk radio, began to argue that health care

reform—"Obamacare" as opponents came to call it—represented the president's attempt to deliver reparations to black Americans for slavery.

The repeated association between the nation's first black president and his signature legislation racialized the role of government in health care. Michael Tesler (2012, 2016) makes this point convincingly. Cross-sectional, panel, and experimental evidence all converge on the same point: after Obama but not before, opposition to the expansion of government health care was driven in an important way by modern racism (Henderson and Hillygus 2011; Kinder and Chudy 2016). Health care illustrates how a policy, on its face neutral with respect to race, can become racialized, depending on how the policy is framed and how it comes to be understood by the public.

The first three cases of racialization—welfare, crime, and Obamacare—may seem straightforward enough. The last case I will discuss is much less so.

Social Security was established by FDR as part of the New Deal. It is financed largely by payroll taxes and, in sharp contrast to welfare programs, is popular among the American public. Social Security is particularly popular among white Americans who score *high* on measures of prejudice. Nicholas Winter (2008) shows that when it comes to pensions for the elderly, prejudice turns into a force for liberalism, for a more generous welfare state.

According to Winter, the racialization of Social Security has to do with the way the program is presented: as social insurance in return for work; as benefits earned by a lifetime of effort. In the American context, work, effort, determination, and the avoidance of idleness are all linked to whiteness: "Work—and the independent ownership of the fruits of that labor—has historically been at the center of what it has meant to be white in America" (Winter 2006, p. 402).

* * *

What the public thinks about policy is accorded a privileged position in democratic theory. Such preferences are taken to be instructions for what government should and should not do. It is an unfortunate feature of American politics today that in many important domains, the majority group's policy preferences are shaped by prejudice.¹⁸

Prejudice's reach is impressive, but it does not intrude on every political question.¹⁹ Various aspects of environmental policy, including climate change, are untouched by prejudice. The same can be said for LGBT politics. Prejudice also has little to say about abortion, childcare, or sexual harassment. The effects of prejudice on the general trade-off between cutting government spending and expanding government programs appear to be small or negligible; small or negligible on the federal government's responsibility to provide jobs and a decent standard of living; and small or negligible on government health insurance—until, that is, the nation's first black president made reform of the health care system his top priority (Burns and Kinder 2023; Kinder 2023).

All in all, research on prejudice and policy has generated an impressive set of results, identifying both where prejudice matters and where it does not. Crisp empirical regularities of this kind are invitations to theoretical invention, and there has been quite a bit of it here: to account for the features that make a policy more or less likely to be understood in racial terms (e.g., Filindra and Kaplan 2016); to comprehend the nature of correspondence between how a policy is framed and presented, on the one side, and how prejudice is represented in the mind, on the other (e.g., Winter 2008); and to identify the psychological

mechanism or mechanisms responsible for the priming of prejudice (e.g., Tesler 2016; Valenzuela and Reny 2020).

5. RACE AND DEMOCRACY

Political psychology no doubt means different things to different people. To me it means this: the application of concepts, theories, methods, and sensibilities developed in the field of psychology to problems and puzzles of political importance. From this point of view, it would be hard to find a better object of study for political psychology than prejudice.

The study of prejudice and politics is important on theoretical grounds because it informs how we should understand democratic politics in general. Under democracy, citizens are asked to make consequential—consequential in the aggregate—decisions about parties, candidates, and policies. They do so *not*, for the most part, to advance their interests (Sears and Funk 1991; Green 1992) or to promote an ideological program (Converse 1964; Kinder and Kalmoe 2017). Rather, for most of us most of the time, politics is about groups. The decisions citizens make about parties, candidates, and policies arise primarily from the attachments and animosities of group life (Achen and Bartels 2017; Huddy 2013; Kinder and Kam 2009; Mason 2018). In this sense, prejudice presents a rich case for the investigation of a group centered analysis of democratic politics.

On the more practical side, the study of prejudice and politics reveals important aspects of the American political system—what it is, and what it could be. If prejudice could be removed, the polarization and ill-feeling that divides the parties would likely be reduced. In the absence of prejudice, racial differences over policy would narrow, and government would be more generous to the poor, the incarcerated, and the underserved (Alesina, Glaeser, and Glaeser 2004; Piketty 2020; Roemer, Lee, and Yi 2007). If prejudice could be erased, Americans would be more satisfied with their form of government (March 2021) and less likely to reject basic democratic norms (Bartels 2020). Racial division is a threat to democracy itself (Levitsky and Ziblatt 2018; Runciman 2018).

None of this is to deny that the United States has come a long way on matters of race. Discrimination is illegal. Voting rights, taken away during Jim Crow, have been returned. The legal foundations of segregation have been dismantled. Black participation in political life towers over what it was a generation or two ago. By almost every measure, the quality of life experienced by black Americans has notably improved. In 2008, American voters chose Barack Obama, the son of a Kenyan immigrant, as their president.

All true. But it is also true that the United States continues to be marked by deep racial differences. Black children are more than twice as likely than white children to die in their first year. Those who survive face poorer health, more illness—asthma, diabetes, heart disease, and cancer—and, on average, a shorter life. Black adults are twice as likely to be unemployed as whites, and when they are employed, they earn less. On average, black households command about *one-tenth* the financial assets of the average White household.²⁰ For young black men, imprisonment has become more common than military service or a college education (Travis, Western, and Redburn 2014). In poor black neighborhoods, “law enforcement and discipline are now part of the architecture of community life” (Weaver and

Lerman 2010, p. 1). In such places, black citizens contact government primarily in police stations, courtrooms, and prisons (Soss and Weaver 2017).²¹

Inequality is maintained and strengthened by segregation (Anderson 2010; Massey and Denton 1993; Trounstein 2018), and segregation remains a feature of American social life. In 2010, in a typical major American city, one-half or more of the black population would need to re-settle in new neighborhoods in order to achieve racial balance in the city as a whole (Massey and Tannen 2015). If neighborhoods remain segregated, then so do other important institutions: where Americans worship, where they shop, whom they marry, and notably, where American children go to school. In major metropolitan areas in the United States, segregation of schools is increasing (Clotfelter 2004).

African Americans make up roughly 13% of the voting age population in the United States, but they comprise less than 2% of elected officials (Burns and Kinder 2023). Congress re-authorized and strengthened the Voting Rights Act in 1970, 1975, 1982, and 2006, but in 2013, in *Shelby County v Holder*, the Supreme Court weakened two key provisions, arguing that voting rights were no longer threatened by racial discrimination. More recently, in the name of ensuring election integrity, state legislatures under Republican control have passed scores of statutes to make voting more difficult (Berman 2015; Hajnal *et al.* 2017). And after American voters placed Obama in the White House, they turned to Trump.

All of this is a reminder of why the study of prejudice and politics in America remains vital today, some 400 years after the first enslaved people were brought ashore in Virginia. In *Deep Roots*, Acharya, Blackwell, and Sen (2018) show the lingering effect of slavery on Southern whites' racial attitudes today, some 150 years after emancipation. "History," as James Baldwin once wrote, "is not the past. It is the present. We carry our history with us. We are our history."²² So it seems.

NOTES

1. Going against current practice, I do not capitalize "white" or "black." Capitalization encourages the idea that the terms refer to distinct biological races, an idea we should give up.
2. On the mutability and tenacity of racial categories, see Bobo (2011); Davenport (2020); and Liebler, Porter, Fernandez, Noon, and Ennis (2017).
3. I do distinguish racism (or prejudice) considered as an individual attitude from systemic or institutional racism. The latter is enormously important, but racism as attitude is also important, especially in the domain of democratic politics, which is my subject here.
4. Throughout, "white" means non-Hispanic white.
5. For an argument and some evidence that the election of the nation's first black president might be generating a revival of biological racism, see Tesler (2013) and Knuckey and Kim (2015).
6. That I am a protagonist in these discussions places me, given the purpose of this essay, in an awkward position. Here I will just cite several replies to the critics: Kinder (2023); Kinder and Mendelberg (2000); Sears and Henry (2005); Simmons and Bobo (2018); and Tarmann and Sears (2005).
7. Valentino, Neuner, and Vandenbroek (2018) report a small effect of implicit prejudice on opposition to Obamacare; their analysis does not include an explicit measure of

- prejudice. Banks and Hicks (2016) find that a measure of implicit prejudice predicts white support for stiffer restrictions on voting, but only after administration of a fear induction, and without controlling on explicit prejudice.
8. Where measures of modern racism, measured directly, may prove to be less relevant (e.g., Peyton and Huber 2021).
 9. Outside the South, the movement toward racial liberalism among Democratic Party elites started earlier, beginning in the mid-1940s and continuing on gradually and more or less continuously through the racial crisis of the 1960s (Schickler 2016).
 10. According to the American National Election Study.
 11. Obama is bi-racial: his father was black (and dark); his mother was white (and pale). Following convention, most Americans looked at Obama and saw a black man.
 12. Except when Congressional elections feature a black candidate. Then, with partisanship taken into account, black candidates generally run stronger among African American voters—by 4 or 5 percentage points—and weaker among white voters—by roughly 10 percentage points—than they would in the absence of racial considerations (e.g., Bullock and Dunn 1999; Grofman, Handley and Lublin 2001; Lublin 1997; Sass and Pittman 2000; Sass and Mehay 1995).
 13. On the political significance of skin color within the black community, see Ostfeld and Yadon (2022).
 14. One popular alternative interpretation of the 2016 election emphasizes populism, Trump's supposed capacity to speak for the dispossessed, to give voice to those Americans displaced economically and ignored politically. Researchers who have looked for populism as a basis for the Trump vote have found very little evidence for it (e.g., Mutz 2018; Reny et al. 2019; Sides, Tesler, and Vavreck 2018). An exception is Baccini and Weymouth (2021), who find that Trump did better among whites living in counties suffering sharp losses in manufacturing jobs. A second alternative account emphasizes Trump's history of misogyny. The evidence here is stronger. Voters committed to the traditional view of women's place tended to vote for Trump, and so did those who expressed resentment over what they took to be women claiming special rights. These effects showed up in the 2016 election, but not before, and appear to be traceable more to Trump than to Clinton (Kinder, Reynolds, and Burns 2019; Schaffner, MacWilliams, and Nteta 2017; Valentino, Wayne, and Ocenio 2018).
 15. Robert Kagan, *Washington Post*, May 20, 2016, A21.
 16. Another aspect of what Enos calls "social geography" is proximity to protest. Omar Wasow (2020) found that in presidential elections between 1964 and 1972, whites living in counties close to nonviolent black protests (which often provoked violent counter measures from white authorities) tended to vote more Democratic than comparable whites living far from such protests. Proximity to *violent* black protest appears to be another matter. According to Wasow, violent protest pushed whites to vote more conservatively. In a close analysis of the violence in Los Angeles set off by the Rodney King verdict, Enos, Kaufman, and Sands (2019) report the opposite.
 17. On the responsiveness of national policy to public opinion, see, among others, Miller and Stokes (1963); Bartels (1991, 2016); Stimson, MacKuen, and Erikson (1995); Gilens (2012); and Lenz (2013).
 18. In all these cases and more: aid to Africa (Baker 2015); the Confederate flag (Strother, Piston, and Ogorzalek 2017); trade policy (Mutz et al. 2021); paying college athletes (Wallsten et al. 2020); support for the Iraq War (White 2007); restricting voting (Banks

- and Hicks 2016; Wilson and Brewer (2013); on how Americans think of themselves ideologically (Ellis and Stimson 2012; Kinder and Kalmoe 2017); pocketbook voting (Crowder-Hersh and Nall 2020); and tax reform (Burns and Kinder 2021).
19. At least not directly. As argued earlier, prejudice is implicated in partisanship. To the extent partisanship shapes opinion on the matters mentioned in the text, to that extent so does prejudice.
 20. The literature on racial differences in economic status is enormous. See, among many others, Blank (2001) and Farley and Allen (1987). On race and health, see Williams (2001) and Xu, Murphy, Kochanek, and Tejada-Vera (2021).
 21. Nearly everyone who is sent to prison eventually gets out. Mass incarceration means a corresponding huge population of the formerly imprisoned are “at large.” They are at large but with impaired prospects, including forfeiture of voting rights. Following felony convictions, offenders are typically stripped of the right to vote. Many of the statutes governing disenfranchisement were passed in the late 1860s and 1870s, at a time when the question of voting rights for black Americans took on special urgency, and are most common in states with large nonwhite prison populations (Behrens, Uggen and Manza 2003; Uggen and Manza 2002). Because black Americans are much more likely to be arrested, convicted, and incarcerated than whites are, blacks are also much more likely to have their voting rights revoked on this ground (Weaver and Lerman 2010).
 22. From *Remember This House*, notes for Baldwin’s unfinished book on the intertwined lives of three murdered friends: Medgar Evers, Martin Luther King, Jr, and Malcolm X.

CHAPTER 28

MIGRATION AND MULTICULTURALISM

EVA G. T. GREEN AND CHRISTIAN STAERKLÉ

UPON its publication in news outlets around the world, the picture of the body of Alan Kurdi—a three-year-old Syrian refugee boy washed up on a Greek beach in September 2015—instantly led to a global upturn in concern and awareness of the risks and misery of migration. Despite the controversies around the circumstances of the picture and the reactions to it, migration was now on everyone's mind. This is but one tragic event among uncountable others around the world through which migration and multiculturalism forced their way into global consciousness over the last decade. There were terror attacks against migrant minorities, racist incidents, hate speech against immigrant groups, and electoral successes of radical right parties. But there were also powerful reactions against such exclusionary tendencies. In many countries, people mobilized to show solidarity with refugees and organized into collectives to defend the rights and dignity of the ever-growing masses of migrants (de Haas et al., 2019).

Migration and multiculturalism have become key issues over which contemporary societies are increasingly polarized. The negative reactions to migratory flows have become more radical, but supporting movements have also made their voices increasingly heard (Bloemraad & Voss, 2020). Indeed, virtually all countries in the world need to deal with the steady flow of people crossing international borders that have made societies in our globalized world more and more diverse. Despite its contested nature as a normative model for organizing diversity in receiving societies, demographic multiculturalism has become a reality to which countries need to adapt.

This chapter focuses on two major questions concerning migration and multiculturalism. First, it looks at the social and psychological processes at work in the migrant experience. Second, it deals with how members of receiving societies react to the increased and diversified immigrant presence in their societies.¹ Our review draws mainly upon research and theory in political and social psychology. Reflecting the diversity of classic and recent empirical work on migration and multiculturalism, we present research covering a wide range of methodological approaches, including survey, experimental, and qualitative studies. The chapter emphasizes how historical and political contexts affect the nature of intergroup relations between migrant groups and receiving societies. It furthermore

highlights the role of widely shared social representations in processes of migration and multiculturalism, expressed in ideological belief systems, political discourse, and everyday cultural repertoires. We argue that a political psychology perspective to migration and multiculturalism will gain from taking an interdisciplinary approach in which different levels of analysis—including individual, group and societal factors—are combined and articulated (de Haas et al., 2019; Chrysoschoou, 2004; Deaux, 2006; Verkuyten, 2018).

The chapter is organized in four parts. The first part outlines some historical benchmarks of modern migration and briefly presents two key notions of a psychological approach to migration—assimilation and multiculturalism—in their historical context. In a second part, we summarize empirical research that focuses on the psychological dynamics involved in the migrant experience, in particular the interactionist and complex nature of migrant identities, acculturation in receiving societies, and intergroup approaches to acculturation and multiculturalism. The third part analyzes the role of threat regarding immigrants and immigration in the reactions of majority populations in receiving societies. The fourth part presents multilevel research on the effects of contextual factors on attitudes toward immigration held by national majority groups.

Since other chapters in this volume are directly concerned with processes related to historical ethnic minorities within countries (Kinder, Chapter 27, this volume), this chapter specifically analyzes diversity and multiculturalism as the outcome of international migration. Moreover, although migration is a global phenomenon, we focus our discussion mainly on those migration flows which end up in Western countries, since it is mostly in these contexts that empirical research has studied the psychological processes involved in the migrant experience and the public reactions to immigration.

1. ASSIMILATION AND MULTICULTURALISM IN CONTEXT

Early works on acculturation and incorporation of immigrants (e.g., Park & Burgess, 1921; Thomas & Znaniecki, 1918) reflected questions arising from voluntary and permanent forms of migration, especially to the United States. Incorporation of immigrants in the host society was seen as a one-way street toward the hegemonic White Anglo-Saxon Protestant “WASP” norm in which immigrants gradually lose their ties with their country of origin while picking up the values of the receiving society. In this model of migrant *assimilation*, the identity of origin was to be replaced with the host identity, and ethnic distinctions as well as the cultural and social practices that express it were bound to disappear (see Alba & Nee, 2003, for a more contemporary analysis of assimilation). Assimilation therefore relies on the principle of *similarity* between migrant groups and the receiving society: Such intergroup similarity is deemed to foster successful integration into mainstream society and to promote harmonious intergroup relations within receiving societies. Largely taken for granted in the early times of immigration, it was the sole conceivable form of migrant incorporation. Metaphors such as *melting pot*, *soup*, *stew*, and *salad bowl* have been put forward to figuratively describe variants of assimilation. Their relevance, however, is contested, as their use depends on the (perceived) degree of dissolution of the original ethnic and

national identities and their absorption in mainstream society as well on the (perceived) emergence of new cultural identities.

European diversity, in contrast, is historically due to migration from former colonial countries and the presence of different cultural and linguistic groups on national territories, for example Wallonian and Flemish populations in Belgium, or Finnish- and Swedish-speaking and native Sami populations in Finland. In “multi-nation” states where cultural diversity arises from the incorporation of territorially concentrated cultures into a larger state, the political debate has been more concerned with political rights of resident cultures than with their assimilation into receiving societies (Kymlicka, 1995). In these contexts, minority cultures typically claim self-government rights that demand some form of political autonomy (e.g., the province of Quebec in Canada or Catalonia in Spain) or special representation rights in order for the groups’ views and interests to be effectively represented in the political process, for example by allocating a predefined number of seats in the legislature for members of minority groups (Azzi, 1992).

After WWII, the nature of international migration gradually changed. Migration volume increased drastically, due to armed conflicts and large-scale natural disasters, growing global inequalities pushing people to search for a better life, or new international agreements liberalizing person movements (de Haas et al., 2019). The United States was confronted with new waves of mass immigration from Latin America (especially Mexico), Asia, and the Caribbean after the Immigration Act of 1965. Part of this migration was characterized by large numbers of undocumented “illegal” immigrants, by religious identities different from those of American mainstream society, by a tendency to maintain closer ties with their countries of origin, and often by a reluctance or incapacity to learn the English language. Thus, in the 21st century, migrants originate from increasingly diverse economic, social, and cultural backgrounds, giving rise to differentiated forms of migration in receiving countries, including voluntary and involuntary migration, temporary and permanent labor migration, as well as refugee, asylum seeker, and family reunion migration. Migration has also become increasingly politicized, in particular with respect to domestic politics which are ever more marked by public debates about immigration (in particular Muslim immigrants), by the tendency of political parties in the Western world to define their identity through tough stances toward migration and multiculturalism, and by hostile, racist, and xenophobic attitudes of large segments of national majority populations in receiving societies (de Haas et al., 2019; Staerklé & Green, 2018). The classical understanding of assimilation as a general settlement policy has therefore become ever more questioned. In this context of “new immigration,” immigrants can no longer be seen as definitely leaving their country of origin or permanently taking residence in the receiving society, the receiving society cultures have become too heterogeneous to provide a single cultural model toward which immigrants should strive, and in light of the difficult experiences of increasing numbers of immigrants, the notion of inevitable assimilationist progress has become untenable (Bornstein, 2017; Deaux, 2006; Vertovec, 2007).

Analyzing policy responses to such criticism, Brubaker (2001), for example, observes the rise of new forms of assimilation policies that no longer expect immigrants to be completely absorbed in the receiving society. These civic integration policies place a stronger emphasis on the progressive process rather than on the desired end-state of becoming similar to the receiving society, for example in the form of proposed or encouraged language courses for immigrants, the acquisition of work-related skills, or the easing of strict naturalization rules

(Joppke, 2017; Lesinska, 2014). These policies focus on individual rights and responsibilities, placing little emphasis on multicultural principles such as cultural recognition and measures to address group-based inequality such as affirmative action. As a result, many countries that formerly had a strong policy emphasis on multiculturalism such as the Netherlands, Sweden, and Australia have shifted to policies that require more “adaptation” and “integration” from immigrants, often under pressure of rising right-wing populist parties (Joppke, 2007; for a related discussion on nationalism see Huddy, Chapter 21, this volume).

The more encompassing response to the limitations of an assimilationist view of migrant incorporation was the gradual development of “difference”-based conceptions of citizenship, based on the formal recognition of migrant and other minority identities and legal accommodation of their difference (Isin & Wood, 1999; Taylor, 1992). One of the major models of this differentialist turn (Brubaker, 2001) was *multiculturalism*, a term that covers multiple realities and presents a number of ambiguities (see Berry, 2013; Glazer, 1997; Kymlicka, 2012).

Multiculturalism has three components (e.g., Ward et al., 2018). First, in a descriptive, demographic, sense, multiculturalism refers to the diverse ethnic composition of contemporary societies, be they the product of existing ethno-cultural groups within countries or the outcome of international migration. In this sense, virtually all countries in the world are multicultural. Second, in a normative and prescriptive sense, multiculturalism is a desirable way of organizing diversity within a country. Offering a positive view of cultural identity maintenance, it considers that cultural diversity *as such* has positive effects on a society, by contributing fresh perspectives, promoting openness toward others, and preventing discrimination (Kymlicka, 1995). Third, multiculturalism is implemented with specific policies that accommodate claims for the recognition of group-specific identities, for example, rights for political representation, legal protection of cultural practices, or language and educational rights. Such group-differentiated policies formally recognize the legitimacy of differences between ethnic and cultural groups residing in a country and aim at promoting equal treatment and equal rights of these groups (Kymlicka, 1995). The passionate debates about the legitimacy of civil, social, or political rights of specific migrant groups, for example affirmative action policies or group-specific clothing regulations (e.g., concerning headscarves and veils of Muslim women, Joppke, 2009) reveal that the question of group rights is one of the most pressing issues in contemporary societies struggling with multicultural demands (Bloemraad, 2015; 2018; Koopmans et al., 2005).

Much like assimilation, the normative model of multiculturalism has come under increasing pressure (Bloemraad et al., 2008; Lesinska, 2014; Joppke, 2014; Kymlicka, 2012). Multiculturalism is accused of undermining national cohesion, exacerbating intergroup divisions rather than overcoming them, essentializing and reifying group boundaries, and ultimately compartmentalizing ethnic groups into segregated urban ghettos (Barry, 2001). As a result, multiculturalism might fuel negative attitudes toward migrant groups rather than alleviate them, as implied by the sweeping declarations from several heads of government over the last 15 years who announced that “multiculturalism has failed” and even suggested that it represents a danger for Western liberal democracies (see Bloemraad, 2015).

Negative effects of ethnic diversity on social relations have also been put forward by Putnam (2007) in the context of his developing the advantages of “social capital.” His “constrict hypothesis” states that ethnic diversity within a given context results in fewer social relations in general, that is, independently of ingroup and outgroup membership, and thus

in weakened social cohesion (for a related discussion on diversity and authoritarianism, see Feldman & Weber, Chapter 20, this volume). Yet, empirical evidence for the “constrict hypothesis” is far from consistent. In a meta-analysis on the alleged detrimental effects of ethnic diversity on social cohesion, van der Meer and Tolsma (2014) found support for the constrict claim for aspects of social cohesion at the level of neighborhoods only, but no consistent evidence for the hypothesis that ethnic diversity would be related to less interethnic social cohesion at more inclusive levels of categorization. Bloemraad (2015) praises the advantages of multiculturalism, arguing that “countries with more multicultural policies and a stronger discourse of pluralism and recognition are places where immigrants are more likely to become citizens, more trusting of political institutions, and more attached to a national identity,” thereby giving them the opportunity “to shape political discourse and policy to be more inclusive of diversity” (p. 593).

Nevertheless, there is broad consensus that multiculturalism is “on the retreat” (Kymlicka, 2010). However, the exact forms and reasons behind this development are disputed as are the alternatives to multiculturalism. For Joppke (2014), “. . . [M]ulticulturalism is under attack today for condoning, even reinforcing a stance in which one’s primordial group attachment [. . .] ranks above one’s civic attachment to the political community” (p. 293). Multiculturalism’s retreat is generally linked to the growing presence of Muslims and Islam in contemporary immigrant integration debates, and the stigma attached to them among more traditional Europeans and North Americans. Putting this development into perspective, Brubaker (2013) argues that “religion has tended to displace language as the cutting edge of contestation over the political accommodation of cultural difference—a striking reversal of the longer-term historical process through which language had previously displaced religion as the primary focus of contention” (p. 16). This shift from linguistic to religious lines of demarcation has been accompanied by the increasing securitization of state-minority relations whereby immigrants are primarily perceived as a threat to the security and cultural integrity of destination societies (de Haas et al., 2019, p.11). This process has been most evident with immigrants of Muslim origin.

There is, however, debate as to whether the ensuing retreat from multiculturalism is a rhetorical “perception” problem or whether there is actual incompatibility and thus real conflict between Islamic and liberal democratic principles (Joppke, 2014; see also Bloemraad, 2018; Banting & Kymlicka, 2013; Malik, 2015). These concerns are to some extent addressed by the concept of *interculturalism* that has recently been advocated as an ideological and policy alternative to multiculturalism (Yogeeswaran et al., 2021). Interculturalism underscores the importance of dialogue and interactions between people of different origins, recognizes mixed and flexible identities, and focuses on similarities rather than on differences between groups (see also Verkuyten & Yogeeswaran, 2020).

The emergence of *transnationalism* and diaspora communities is another key feature of contemporary migration (Faist et al., 2013; Portes & Rumbaut, 2006). Owing to modes of online communication and decreasing travel costs, migrants now can more easily maintain relationships with their societies of origin across national borders. Transnational social spaces are expressed in political engagement of migrants in their country of origin, as financial support for homeland networks, or as regular travel between the receiving society and the country of origin. Transnationalism thereby de-emphasizes the importance of physical location of migrants in the receiving society and extends multiculturalism and ethnic loyalties across the national borders of the receiving society.

In sum, the two major paradigms of migrant incorporation—assimilation and multiculturalism—are both questioned for a variety of reasons. In the following section we will unpack the implications and responses to this development. Focusing on the migrant perspective, we first discuss the formation of contemporary ethnic and cultural identities as well as the strategies deployed to construe migrant identities. We then provide an overview of classical and recent research on acculturation, and finish with a section on contrasting attitudes between minorities and majorities toward cultural diversity and multiculturalism.

2. THE MIGRANT EXPERIENCE

2.1. Contemporary Migrant Identities

The concept of *ethnic identity* captures the dynamics that are involved in the negotiation of cultural and ethnic boundaries in receiving societies (see Verkuyten, 2018). Ethnic identities involve beliefs in commonality, or shared kinship or ancestry; they are historically defined and involve a sense of temporality and continuity that sets them apart from other social identities (see Sani, 2008; for more on the development of ethnic identities see Sears and Brown, Chapter 3, this volume). Yet, in contemporary research, ethnic groups are not bounded cultural entities to which people naturally belong but are rather *social constructions* that emerge from continuous social interactions *between* the migrant and the majority group and *within* migrant groups themselves (Barth, 1969). Migrant identities are therefore the product of both “other-definition” and “self-definition.” *“Other-definition means ascription of undesirable characteristics and assignment of inferior social positions by dominant groups. Self-definition refers to the consciousness of group members of belonging together on the basis of shared cultural, religious and social characteristics. The relative strength of these processes varies. Some minorities are mainly constructed through processes of marginalization (which may be referred to as racism or xenophobia) by the majority or dominant group. Others are mainly constituted on the basis of cultural and historical consciousness (or ethnic identity) among their members”* (de Haas et al., 2019, pp. 76–77). As a consequence of this interactionist view, ethnic group boundaries may be legitimized and maintained (as in multicultural discourses) or on the contrary challenged and eventually dissolved (as in assimilationist and interculturalist discourses).

Reconfigurations of migrant identities are for example contingent upon normative pressures to conform to ingroup obligations (such as the maintenance of cultural traditions) and to outgroup expectations (such as labor market integration). These negotiations may take place between first- and second-generation immigrants, between parents and children, or between high- and low-status group members (Bornstein, 2017). As a result, any characteristics, beliefs, or practices associated with ethnic groups may change over time, for example when longstanding traditions are replaced with modern customs.

Discrimination and stigmatization by the majority group has been shown to be one of the key drivers of more and less inclusive ethnic boundaries (Wimmer, 2013). Research on ethnic identification has indeed shown that the subjective importance of membership in an ethnic group is particularly strong for migrant groups in receiving societies in which the legitimacy of their norms and values—and even their mere presence on national

soil—is questioned. In a study on religious identification by Muslim (Sunni) migrants in the Netherlands, Verkuyten (2007) found that over half of the participants had the highest possible score on scales of religious identification. For these “total” identifiers, identification with the receiving Dutch society was lower than for those Muslims with lower levels of religious identification. These findings suggest that Muslim migrants are prone to stress their ethnic identity in a context of increasing tensions with the receiving society. Hence, the degree and nature of ethnic identification by migrant groups is flexible and is moderated by the intergroup context in receiving societies.

As a result of this dynamic and interactionist view of the formation of ethnic identities, migrant identities are often “messy” and group boundaries “blurry” (Alba, 2005), especially those of second-generation immigrants (see Lamont & Molnar, 2002). The variety of migration contexts, in terms of countries of origin and receiving societies, of migration history, and of duration of residence and political grievances, gives rise to a wide range of possible migrant identity configurations and forms of interdependence between migrant groups and receiving societies (Bornstein, 2017). Contemporary migrant identities combine cultural origins in different ways and thus give rise to new and complex identities, described as multiple, mixed, hybrid, or hyphenated identities (Deaux, 2006; Chen et al., 2008; Phinney, 1990; Verkuyten, 2018). Increased ethnic mixing and the prevalence of multiethnic identities are also reasons why the rigid split between a White majority and Non-White minorities in the United States is a politically motivated and misleading narrative that aims to mobilize support for the far-right myth that non-White minorities would soon outnumber the White majority (Alba et al., 2021).

This emphasis on intergroup mingling and blending stands in stark contrast to classical intergroup research in social psychology that treats social categories as unproblematic and defines them with unambiguous boundaries, possibly reflecting the extensive intergroup research on American race relations where the group boundaries of African Americans are unusually impermeable and fixed. Research on “black exceptionalism” has indeed shown that immigrant groups such as Latinos assimilate more easily into the broader society compared to African Americans (Sears & Savalei, 2006; Citrin & Sears, 2014). More generally, these findings suggest that perceptions of fixed “color lines” of immigrant groups may contribute to maintain minority distinctiveness and to restrict their possibilities for greater assimilation in the receiving society.

The issue of category labeling illustrates the often-difficult task of using appropriate names for migrant categories whose status in the receiving society is changing. Category labels are malleable and strategic constructs, they can make a statement about the norms, values, and cultural history of the group, and they can convey a sense of position of the group in the larger society (Pérez and Vicuña, Chapter 25, this volume; Reicher & Hopkins, 2001). Examples include the continuous debate about the use of “Latino” (or “Latinx”), “Hispanic,” or hyphenated category labels (e.g., “Mexican-American”) to describe immigrant groups of Spanish and Portuguese descent in the United States (Deaux, 2006; Portes & Rumbaut, 2006), or the shift in usage from “Negroes” to “Blacks” to “African-Americans” (Philogène, 1999).

2.2. Identity Work and Identity Negotiation

One of the striking features of migrant identities is the typically large gap between the way migrant groups are categorized by national majorities and by migrant groups themselves.

National majority discourse appeals to inclusive and generalizing categories with often negative connotations such as “foreigners” or “immigrants” (Kosic & Phalet, 2006), while migrants themselves use more fine-grained and less inclusive categories, distinguishing for example between different religious orientations, national and regional origins, or first-, second-, and third-generation immigrants (e.g., Sears et al., 2003).

Discursive research examines such identity constructions through the analysis of language and discourse related to the migrant experience (see Hopkins, Chapter 9, this volume). It thereby explores the multiple meanings social actors attempt to convey when talking about their own and other groups. In this approach, migrant experiences are contextualized within particular social settings and migrant identities are analyzed as flexible and dynamic resources that change as a function of the intergroup context and the historical and political conditions of receiving societies. The analysis of situated discursive practices thus enables a nuanced analysis of the subjective understanding of the migrant experience, such as a low-status position within the receiving society or the suffering of discrimination (Deaux, 2006; Verkuyten, 2018).

In a study based on a discursive approach to social identity theory, Hopkins and Kahani-Hopkins (2004) illustrate how widespread majority representations of a homogeneous and unified Muslim category are challenged by Muslim activists in Britain: some activists put forward a political understanding of Muslim identity and restrict the boundaries of Muslim identity to those members who conform to central Muslim practices such as the Hajj (the Mecca pilgrimage) or the daily prayers. Others, in contrast, promote a more inclusive and spiritual view of Muslim identity and feel affiliated with “people [throughout the world] who are struggling to have their voices heard” (p. 53, see also Hopkins & Greenwood, 2013 on identity performance). The formation of ethnic minority identities as a function of an ongoing negotiation and opposition to stereotypical understandings on behalf of the majority group has been demonstrated by a study on British mixed-heritage children and adults who flexibly construe their identities in the context of inherent tensions of a multicultural community (Howarth et al., 2014). A study on ethnic category label use before and after migration further illustrates the dynamic and strategic formation of ethnic identities as a function of a changing intergroup context. Ethnic Finnish migrants emigrating from Russia to Finland mostly presented themselves as “Finns” in the (Russian) pre-migration context, whereas after their arrival in Finland, their Finnish identity was problematized as they were often viewed by the receiving Finnish society as the “Russians” (Varjonen et al., 2013).

2.3. Acculturation and Multiculturalism

Acculturation research focuses on the determinants and consequences of different strategies migrants employ to adapt to new cultural milieus (see Brown & Zagefka, 2011; Ward & Geeraert, 2016). It has its roots in cross-cultural psychology and studies the individual- and group-level changes resulting from intercultural contact. The classical definition states that acculturation refers to “*those phenomena which result when groups of individuals having different cultures come into continuous first-hand contact, with subsequent changes in the original culture patterns of either or both groups*” (Redfield et al., 1936, p. 149).

The most influential model of acculturation has been proposed by Berry (1990). His model emphasizes the bi-dimensional nature of acculturation processes where the maintenance of relationships with one’s country of origin and the development of new ties

with the receiving society are independent of each other and may therefore combine in different ways. Four basic types of acculturation strategies result from crossing these two dimensions: *integration* reflects a desire to simultaneously maintain ties with the country of origin and establish strong contacts with members of the receiving society, whereas *separation* denotes the wish to maintain one's migrant identity while minimizing contacts with the receiving society. *Assimilation* refers to the abandonment of one's original cultural identity and the pursuit of contacts with the receiving society, whereas *marginalization* describes the rejection of both the original culture and the receiving society.

Due to its important heuristic value, Berry's highly successful model became the starting point of a burgeoning literature on acculturation (see Sam & Berry, 2016). At the same time, various limitations of this initial model have been pointed out over the years, for example that it obscures the wide array of possible forms of interdependence between migrant groups and the receiving society, or that it is not sufficiently sensitive to issues of measurement and operationalization of acculturation orientations (see Bornstein, 2017). Varying operationalizations indeed reflect different degrees of closeness and different levels of involvement with the receiving society, thereby highlighting the difficulty of defining unambiguous criteria of intergroup similarity, an issue already recognized by Gordon (1964) in his classical theory of assimilation. There he differentiated multiple (e.g., cultural, linguistic, behavioral, attitudinal, and identity) dimensions of assimilation. Not surprisingly, then, the rather general measures of endorsement of different acculturation strategies are controversial (e.g., Arends-Tóth & Van de Vijver, 2006).

Flourishing research over the last three decades has amply demonstrated that acculturation is a highly context-dependent, longitudinal, and differentiated process. Based on an extensive overview of the acculturation literature, Bornstein (2017) summarizes these developments of Berry's initial model by developing a "specificity" principle of acculturation science that urges researchers to study the "where, whom, how and when" dimensions of acculturation, that is, to take into account the multiple moderating factors of actual acculturation processes and experiences of migrants. Five moderating terms are identified, *setting* conditions (reasons to migrate, conditions in the cultures of origin and destination, migrants' experience and status), *personal attributes* (gender, individual differences), *time* (age, historical conditions), *process* (socialization, opportunities, participation), and *domain* (multidimensionality of acculturation process). Taken together, the analysis of these factors offers a useful blueprint for a more pluralistic, realistic, and comprehensive perspective than the one-size-fits-all principle of the universalistic taxonomy of individual acculturation choices underlying Berry's initial model.

Much of more recent acculturation research has developed and extended the initial acculturation model to give rise to new theoretical models that are sensitive to the varying experiences of contemporary migrant groups. A first major extension of Berry's model was the *Interactive acculturation model* (IAM, Bourhis et al., 1997; Bourhis et al., 2010). This model adds to the acculturation *orientations* adopted by migrant groups the acculturation *expectations* held by members of the receiving society toward specific groups of immigrants. At one extreme, members of the receiving society may for example expect immigrants to fully abandon their original culture and follow an assimilation strategy. The IAM further adds *individualism* as an alternative strategy to marginalization, denoting an orientation that stresses personal characteristics rather than group membership in both migrant and receiving society acculturation orientations.

The IAM is but one of many acculturation models highlighting the intergroup nature of acculturative processes through “*which majorities and minorities, immigrants and nationals, are engaged in continuous mutual contact and interaction, affecting each other’s acculturative choices and acculturative expectations*” (Horenczyk et al., 2013, p. 205). As already implied in the original definition of acculturation by Redfield and colleagues in 1936, these models recognize that not only the immigrants, but also the receiving society undergo transformations as a result of the arrival of immigrants, thereby emphasizing mutuality in attitudes, perceptions, and expectations (for overviews, see Horenczyk et al., 2013; Brown & Zagefka, 2011). That mutuality is the essential insight behind the familiar “melting pot” metaphor.

Following the mutuality principle, a large body of research has investigated the individual and social factors that determine the preferences for acculturation strategies by (migrant) minorities and majorities (see Ward & Geeraert, 2016, for the ecological context of acculturation). Early studies have found that integration and separation are the preferred modes of acculturation among minorities, whereas majorities expect migrants to endorse either integration or assimilation strategies, though context-dependent exceptions to these patterns are common (see Brown & Zagefka, 2011). A number of factors have been shown to account for the endorsement of acculturation expectations by majorities, including strength of ethnic and national identification, ethnocentrism, social dominance orientation (henceforth, “SDO”), political orientation, feelings of threat from the presence of migrant groups, individual networks of ethnic contacts, or perceptions of immigrant discrimination (e.g., Bourhis et al., 2009; Montreuil et al., 2004). Furthermore, acculturation expectations adopted by majorities depend on the type of migrant groups: integration is likely to be the preferred strategy for “valued” minorities (in terms of favorable stereotypes associated with them), while assimilation, segregation, and marginalization are more likely to be endorsed for negatively evaluated minorities (Montreuil & Bourhis, 2001).

Other research adopting an intergroup perspective has examined the effects of match and mismatch between acculturation orientations held by migrant groups and receiving societies (van Oudenhoven et al., 2006; Brown & Zagefka, 2011; Schwartz et al., 2014). Minority and majority attitudes toward acculturation can either be concordant and give rise to consensual relations between majorities and minorities (especially when both groups agree on integration or assimilation as preferred modes of acculturation), or discordant, evidenced by a mismatch between minority preferences and majority expectations, leading to problematic or even conflictual relationships (Bourhis et al., 1997). The relational outcomes of a mismatch of intergroup definitions of acculturation orientations include, for migrants, heightened acculturative stress, and, for members of the receiving society, stereotyping and discriminatory behaviors, for example in educational or health care institutions, at the workplace, in housing decisions, or in encounters with the police.

Such mismatch was evidenced in the Netherlands, where Moroccan and Turkish immigrants have been shown to prefer integration, while Dutch nationals believed that separation, their least liked orientation, was mainly chosen by these migrant groups (van Oudenhoven et al., 2006). In Germany, research has similarly shown that whereas migrant groups preferred strategies implying contact with the receiving society, majorities thought they endorsed strategies implying culture maintenance (Zagefka & Brown, 2002). More importantly, this study revealed that greater perceived mismatch between migrant and majority acculturation orientations at the individual level deteriorated the perceived quality of

intergroup relations (in terms of ingroup favoritism and perceived discrimination) for both minorities and majorities.

The intergroup nature of migrant incorporation in receiving societies is also evidenced at the level of public opinion about multiculturalism and the policies destined to implement its principles. One of the key findings of this strand of research is that ingroup identification by minority groups is associated with identity affirmation and the support for multicultural, group-differentiated policies, whereas ingroup identification with majority groups strengthens perceptions of the threatening aspects of multiculturalism and thus opposition to group-based claims and policies (see Verkuyten, 2018). This pattern of findings has become known as the “multiculturalism hypothesis.” It has received experimental support in studies where multicultural vs. colorblind ideologies have been manipulated (Wolsko et al., 2006; for a general review of cognitive effects of multiculturalism, see Crisp & Turner, 2011).

The common finding that support for multicultural policies is higher among migrant groups than among national majorities further suggests that minorities and majorities endorse different justice conceptions. Following early work on minority rights and procedural justice in South Africa by Azzi (1992), recent research has indeed demonstrated that membership in subordinate minority groups generally increases perceived compatibility between individual and collective forms of justice (Gale & Staerklé, 2019). In other words, majority natives are likely to reject multicultural policies when they view society as a space of individual competition, but less so when they question the primacy of individual justice principles. For immigrants, in turn, attitudes toward inequality-reducing multicultural policies do not depend on beliefs in individual responsibility. Indeed, their subordinate position leads them to consider that their successful integration in society requires endorsement of both individual and collective justice principles (Simon, 2011).

2.4. Successful and Unsuccessful Acculturation

Much work on acculturation has been concerned with the factors that determine whether acculturation is successful or not, that is, whether migrants are able to appropriately negotiate the demands of the receiving society and adapt to a new cultural context (see Nguyen & Benet-Martínez, 2013). Successful long-term adaptation is multidimensional and evidenced with migrants’ sociocultural and political integration, labor market integration, psychological well-being, and physical health. Cultural learning approaches highlight the necessity to learn culture-specific skills in order to successfully adapt to a new cultural milieu, in particular communication competence such as proficiency in the language of the receiving society (Jasinskaja-Lahti, 2008) and effective social interaction skills (Masgoret & Ward, 2006). Extensive social support further increases migrant well-being and adjustment (Safdar et al., 2009), in particular social networks that include members of the receiving society (Jasinskaja-Lahti et al., 2006; Repke & Benet-Martínez, 2018). Illustrating the importance of transnational social spaces as determinants of successful adaptation, ethnic networks *abroad* have also been shown to increase migrant well-being (Jasinskaja-Lahti et al., 2006).

Acculturation is a gendered process, since girls and boys, and women and men, acculturate differently. Notably, women tend to be more distressed by interpersonal difficulties common after migration, but men are more concerned by discrimination, financial worries,

and work-related adversities (see Bornstein, 2017). Exposure to majority norms and expectations also has gender-specific implications (Bos and Schneider, Chapter 19, this volume). For example, the confrontation with gender equality norms of Western societies affects girls and boys differently, especially those immigrant children from traditionally gendered societies (Suárez-Orozco & Qin, 2006). Under such circumstances, sons may experience greater achievement and cultural conformity pressures than daughters. Gender further shapes majority responses to immigrants, for example Dutch girls have been found to be less concerned with ethnic group differences and more likely to consider immigrant children as Dutch than are their male counterparts (Verkuyten et al., 2013).

Acculturative stress, in turn, may result from unsuccessfully negotiated cultural contact and manifest itself as depressive symptoms, feelings of anxiety, and psychosomatic disorders (Berry, 2006). Following Berry's initial framework, research has generally shown that integration is the most, and marginalization the least, adaptive strategy to deal with acculturative stress. That is, the integration strategy leads to the most positive outcomes in terms of coping, psychological health, and well-being (Berry & Sabatier, 2010; Nguyen & Benet-Martínez, 2013). Yet, processes of adaptation develop over time, with acculturative stress increasing soon after the arrival of the migrant in the receiving society, followed later by a decrease over time (Berry, 2006).

A key factor underlying successful adaptation is the experience and perception of *discrimination* among migrants. There is ample empirical evidence showing that perceiving oneself as a target or victim of majority discrimination is a major acculturative stressor, increasing depressive symptoms, distress, and anxiety, as well as decreasing life satisfaction, well-being, and self-esteem (Cassidy et al., 2004; Liebkind & Jasinskaja-Lahti, 2000; for a meta-analysis, see Schmitt et al., 2014). In a study on the impact of discrimination on the acculturation strategies of international students in the United Kingdom for example, perceived discrimination has been shown to lead to a perceived lack of permeability of group boundaries, and thus to avoidance of the receiving society and endorsement of one's own cultural background (Ramos et al., 2016). A study examining both pre- and post-migration factors underlying psychological adaptation of ethnic migrants in the receiving society found that pre-acculturative stress and anticipated discrimination (before migration) are associated with subsequent greater stress and discrimination (after migration), which in turn decrease post-migration well-being (Mähönen & Jasinskaja-Lahti, 2012). These findings suggest that migration expectations predict at least to some extent actual psychological and behavioral adaptation in the receiving society. They thus plead in favor of pre-migration interventions to create positive, though realistic, expectations regarding the intergroup context of the receiving society.

Many if not most migrants have to find ways to deal with discrimination in receiving societies, though most often against other members of their group than against them personally. In line with the common finding that threats to the ingroup encourage group identification, perceived discrimination has thus been shown to increase ingroup identification (Jetten et al., 2001; Craig & Phillips, Chapter 23, this volume; Perez & Vicuna, Chapter 25, this volume). The deleterious effects of perceived discrimination may therefore to some extent be buffered through identification with minority groups (see Schmitt et al., 2014).

Subsequently, a more general model of "social cure" has been developed that demonstrates how social identities (and related factors such as social support and a sense of community) are capable of promoting adjustment, coping, and well-being for individuals dealing with

migratory stressors such as discrimination, particularly among vulnerable populations such as migrants (Jetten et al., 2012). In a study on Syrian refugees in Turkey, for example, higher perceived ethnic discrimination was associated with poorer physical and mental health, but these effects were weaker or non-existent for refugees who derived a sense of efficacy and meaningfulness from their Syrian identity, thereby also underscoring the importance of differentiating identity needs for understanding the effects of perceived discrimination (Çelebi et al., 2017).

The positive effects of social identities on well-being are far from consistent, and critically depend on identity content and the social status of the group. In a study on immigrant detention in the United Kingdom, for example, shared identities were a source of burden and distress, because detainees carried guilt, and interactions with other ingroup members were painful (Kellezi et al., 2019). Another study demonstrating the limits of the social cure paradigm found that while Syrian refugees' poor health conditions after their arrival in the United Kingdom was fully explained by emotional distress, social support did not play any role in accounting for longitudinal health conditions (James et al., 2019). Thus, when identities are threatened and stigmatized, and when individual circumstances cause harm to other ingroup members and lead to ostracism, social cure can become a social curse.

Under conditions of successful adaptation, however, individuals may develop dual or bi-cultural identities that represent comfort and proficiency in both the culture of origin and the culture of the receiving society. In an extensive meta-analysis, Nguyen and Benet-Martinez (2013) have found a strong and positive association between bi-culturalism and both psychological and sociocultural adjustment, suggesting that complex identities have generally clear advantages over single identities. These psychological benefits were however contingent upon the countries of origin, with positive associations for Latin American, Asian, and European immigrants, whereas no or negligible associations were found for African immigrants.

Dual identities also have implications for the political integration of migrants into liberal democratic societies. In a longitudinal survey study on Turkish migrants in Germany, Simon and Ruhs (2008) showed that dual identification with the Turkish migrant group and the superordinate German national group uniquely predicted political involvement in the form of support for political claims in favor of Turks living in Germany, while no relation was found between dual identification and radical or violent politicization. These findings suggest that while identification with the aggrieved ingroup is necessary to foster involvement on behalf of the ingroup (Spears et al., 2001), identification with the superordinate group is also required to foster normative collective action, since it reflects the acknowledgement that political action needs to be taken within the limits of general acceptance of the larger polity (see Azzi et al., 2011; Van Stekelenburg & Gaidytė, Chapter 26, this volume, for dynamics of collective action and political mobilization by migrant groups).

Political and legal integration of migrants through the granting of national citizenship represents the final phase of the migration process. Demonstrating the benefits of a multicultural approach to diversity, research has shown that in countries with multicultural policies and pluralistic discourse, migrants are more likely to become national citizens, participate in political decision-making, and identify with the country (Bloemraad, 2015; Politi et al., 2022). Yet, for naturalized immigrants this transition from national outsiders to national insiders may paradoxically lead to more negative attitudes toward other, more recent immigrants. Research has indeed demonstrated that recently naturalized citizens in

Switzerland who expressed belongingness motives to justify their desire to become national citizens were more likely to support restrictive immigration policies compared to those who wished to naturalize for instrumental motives (Politi et al., 2020).

Finally, the socioeconomic position of the migrant is recognized as a key determinant of adaptation as well. “Segmented assimilation” refers to outcomes where migrants are assimilated into different segments of society as a function of social class (Portes & Rumbaut, 2014). For low-status migrants this process may lead to “downward assimilation” whereby young migrants join the most disadvantaged minorities at the bottom of society, an outcome squarely at odds with early assimilationist expectations of upward mobility and integration into mainstream society. Migrants in low social positions have also been shown to experience greater acculturative stress and to be prone to unsuccessful adjustment (Jasinskaja et al., 2006). An important driver of unsuccessful and precarious adjustment concerns low educational achievement of children of immigrants. Research has evidenced large achievement gaps between native and immigrant children and adolescents, often associated with school disengagement and feelings of lack of belonging of immigrant youth (Motti-Stefanidi & Masten, 2013). Recent research shows that a contextual multi-level approach that examines the interplay between identity threat, identity protection, and educational achievement at different levels of analysis is required to account for this achievement gap. Minority educational attainment has thus not only been associated with positive interpersonal relations with peers and teachers, but crucially also with schools that explicitly promote and enact identity-protective institutional values and ideologies such as multiculturalism. Educational acculturation is thus contingent upon identity protection and threat at the interpersonal, intergroup, and institutional level (Phalet & Baysu, 2020).

3. MAJORITY ATTITUDES TOWARD IMMIGRATION: THREAT PERSPECTIVES

The large migratory flows to Europe, the United States, and other parts of the world over the last decades have impacted receiving societies in many ways. Even though the world has witnessed many heartfelt and welcoming reactions to the arrival of immigrants and refugees (as in Germany following the Syrian refugee “crisis” in 2015, see Bloemraad & Voss, 2020), the public debate in receiving societies has been aligned with the securitization turn in migration policy and migration law (de Haas et al., 2020), dominated by anti-immigrant rhetoric that sees migrants and refugees as a “problem,” as a “threat,” or as a “danger.” Immigrants are thus depicted as “flooding” the country, “taking away” the jobs of citizens, abusing the welfare system, or undermining national values (e.g., Every & Augoustinos, 2007). Such allegations imply that the arrival and presence of immigrants yields various negative consequences for citizens of receiving countries. The alleged threats are subsequently used as arguments to oppose rights of immigrants and restrict their entry into receiving societies. Oddly, the voices of those perceiving immigrants as solving labor shortages due to low birth rates in more developed countries have usually been more muted. In this section, we present research that examines the role of perceived threat in explaining the psychological processes underlying attitudes toward immigrants by members of receiving societies.

The notion of threat is present in a plethora of social psychological theories concerned with understanding the underpinnings of anti-immigration attitudes (see Riek et al., 2006; Stephan et al., 2016). Threat is an umbrella term with multiple meanings (Stein, Chapter 11, this volume). Broadly defined, threat appraisals refer to the anticipation of negative consequences related to the arrival and presence of immigrants in a receiving society. Threat research generally differentiates two main routes through which threat relates to anti-immigration attitudes: material or realistic threats on the one hand, and value or symbolic threats on the other (e.g., Riek et al., 2006; Sears & Funk, 1991; Stephan et al., 2016). Material threats anticipate negative consequences with respect to the distribution of valued and usually scarce tangible resources in the receiving society, including economic assets, political power, and physical well-being of national ingroup members. Value-based threats, in turn, foresee perceived non-tangible negative consequences of immigrant presence and are derived from the assimilationist idea that all members of the national ingroup should share the same values and conform to common norms. Threat has also been assessed with intergroup anxiety, involving feelings of uneasiness and awkwardness related to intergroup interactions (Stephan & Stephan, 1985). The psychological nature of threat thus varies, since threat may refer to the perceived likelihood of negative immigration consequences or to an emotional anticipation involving fear and anxiety (Esses et al., 1998; Stephan et al., 2016).

3.1. Material Threats

Some theoretical models focus on locating the causes of anti-immigrant attitudes in the competitive intergroup *structure* of the relationships between the national ingroup and immigrant outgroups. Based on *realistic conflict theory* (Sherif, 1967), these models assume that competition over scarce resources between social groups leads to intergroup conflict and, consequently, to negative attitudes toward immigrant outgroups. As a result, individuals who perceive competition with an immigrant outgroup are most likely to experience material threat and develop negative attitudes toward members of the group. *Group position theory* (Blumer, 1958; Bobo, 1999) and *social dominance theory* (Sidanius & Pratto, 1999) take a similar approach, underscoring that societies are structured as group-based hierarchies in which dominant (usually majority) groups have many advantages over subordinate (immigrant minority) groups (see also Esses et al., 2005). Dominant national ingroups propagate “legitimizing myths” that portray the majority-immigrant relationship as competitive in order to justify their higher status, resources, and power.

Perceived economic threat has been shown to relate to discriminatory attitudes toward immigrants in Europe (McLaren, 2003; Pereira et al., 2010) and North America (e.g., Citrin et al., 1997; Esses et al., 1998), as well as in Asia (e.g., Singapore Ramsay & Pang, 2017) and Africa (e.g., South Africa; Harris et al., 2018). The perceived share of immigrants of the overall population and the anticipation of demographic shifts toward a decreasing proportion of native citizens are variants of perceived realistic threat that drive anti-immigration attitudes and support for restrictive migration policies (Gorodzeisky & Semyonov, 2020; Major et al., 2018; Shepherd et al., 2018; see also Craig et al., 2018; Danbold & Huo, 2015, for similar effects related to the perceived declining share of Whites in the United States). Security threats such as anticipated terrorist attacks are also understood as a form of

realistic threat, mainly fuelling threat perceptions regarding Muslim immigrants (Canetti-Nisim et al., 2009; see Snider et al, Chapter 14, this volume).

3.2. Value Threats

In current-day Western societies, the worldviews of Muslim immigrants are often represented as threatening the core values of receiving societies. In March 2021, for example, a slight majority of the Swiss electorate voted in favor of banning face coverings in public, including the burka and the niqab worn by Muslim women, thereby illustrating the political consequences of such perceptions of value threat. Perceived value threat originates in presumed differences in belief systems, worldviews, and morality between immigrant groups and national majorities (e.g., Sears & Funk, 1991). Purportedly incompatible values of immigrant communities are portrayed as a menace to an idealized, homogeneous national ingroup whose members share common values (Biernat & Vescio, 2005; Esses et al., 2005). Different lines of value threat research converge in the argument that values and norms of the national majority are used as the frame of reference for judging immigrant outgroups (see Joffe & Staerklé, 2007).

Importantly, negative immigration attitudes are often triggered by *perceptions* or *beliefs* about profound value differences rather than by any objective difference. Huntington (2004), for example, argued that the continuing immigration from Latin America threatens the linguistic and Anglo-Protestant cultural identity of the United States, but this culturalist argument is inconsistent with data showing that by the third generation, most Hispanic immigrants identify as Americans and are monolingual in English, and that therefore alleged value differences soon become minimal (Citrin et al., 2007). Yet, exposure to xenophobic threat rhetoric can backfire and make Hispanic immigrants and Latinos in the United States more ethnocentric and less politically trusting, thereby in turn confirming majority threat perceptions (Pérez, 2015).

The origins of immigration attitude research on value threat can be found in theories initially developed to understand the continuing racism against Blacks in the United States. This research has demonstrated that the old-fashioned bigotry from the Jim Crow era has been replaced with a more subtle type of prejudice that is socially more acceptable because it is anchored in Blacks' purported lack of conformity with key American values (see Sears & Henry, 2005; Gaertner & Dovidio, 2004; McConahay, 1986). In symbolic racism theory, for example, Blacks are perceived to violate, more than Whites, traditional American values such as self-reliance, the work ethic, and respect for authority (Sears & Henry, 2005). Pettigrew and Meertens (1995) conceptualized similar ideas in the European context, leading them to distinguish between blatant and subtle forms of prejudice against immigrants. Perceived value violation by immigrants is a central component of subtle prejudice against immigrants, in addition to exaggeration of cultural differences and the denial of positive emotions toward immigrants.

Both symbolic racism and subtle prejudice have been shown to underlie support for various restrictive policies such as expulsion of value-violating immigrants in Europe (Pettigrew & Meertens, 1995) and Whites' opposition to immigration and multilingualism in the United States (Sears et al., 1999; see also Huddy & Sears, 1995). Drawing on this seminal work, value-based threats have been shown to be associated with anti-immigrant

prejudice (McLaren, 2003; Sides & Citrin, 2007; Davidov et al., 2020). For example, a study conducted in the Netherlands showed that perceived symbolic, but not material, threat predicted prejudice against Muslim immigrants (Velasco González et al., 2008; see also Sniderman et al., 2004). Moreover, perceived cultural threats are a stronger predictor of far-right support than are perceived economic ethnic threats (Lucassen & Lubbers, 2012).

3.3. Beyond Material and Value Threats

Although value and material threat are often conceived of as rival explanations of anti-immigrant attitudes, some research suggests that they coexist and are complementary, providing different, but not mutually exclusive, motivational explanations of immigration attitudes (e.g., Riek et al., 2006; Sniderman et al., 2004; Stephan et al., 2016). Empirically, realistic and symbolic threat perceptions are generally strongly correlated (Staerklé & Green, 2018; Stephan et al., 2016) and frequently difficult to disentangle.

A case can be made that both the perception of material and value-based threat relate to the fundamental processes of dealing with intergroup similarity and difference, respectively. Material threat implies that *similarity* with immigrants is threatening since “they” are motivated to acquire the same resources “we” want, too. Value threat, in turn, implies that *difference* with immigrants is threatening, since “they” are too different to be integrated into “our” society. This hypothesis is supported by a study that revealed more negative attitudes toward Mexican immigrants in the United States when participants focused either on intergroup *difference* in positive interpersonal traits such as “generous” and “friendly” (supporting value threat predictions) or on intergroup *similarity* on work-related traits such as “competent” and “hardworking” (supporting material threat predictions; Zárate et al., 2004). These “similar” immigrants may thus evoke material threat, related to the job market (e.g., highly qualified Germans in the German-speaking side of Switzerland), in line with the reactive distinctiveness hypothesis based on social identity theory (e.g., Jetten et al., 2004). Across European countries, symbolic threat was also found to relate to preferences for immigrants similar to oneself, whereas material threat was related to preferences for different immigrants who would not compete for the same resources (Ben-Nun Bloom et al., 2015).

Ideological orientations have been shown to account for some of these different threat effects by shaping the threat experience that subsequently drives anti-immigration stances (Cohrs & Stelzl, 2010; Duckitt, 2006; Guimond et al., 2003). Research in the United States and Switzerland demonstrated that when immigrants were portrayed as adapting to the values of the receiving society (i.e., becoming similar to the national majority), anti-egalitarian (high-SDO) nationals motivated to enforce status boundaries were more willing than low-SDO nationals to persecute immigrants than when they did not make such integrative efforts (Thomsen et al., 2008). In contrast, right-wing authoritarian (RWA) nationals concerned with the enforcement of ingroup norms were more willing than nationals low on RWA to persecute immigrants when they did *not* make integrative efforts.

The way perceived threat affects intergroup attitudes thus depends on the specific immigrant group under consideration. Indeed, Cottrell and Neuberg (2005) have outlined a sociofunctional approach to prejudice arguing that prejudice toward specific outgroups arises from specific forms of intergroup threat. For example, security fears have been

shown to shape attitudes toward Muslim immigrants, but material threat generates views toward eastern Europeans (Hellwig & Sinno, 2017). “Culturally distant” and stigmatized immigrant groups whose members wear visible signs of cultural or religious affiliation, or differ in physical appearance, are the most likely targets of value-based threat rhetoric. This is the case for example for low-skilled Hispanic laborers in the United States or Muslim immigrants, refugees, and Roma people in Europe. Accordingly, immigrants deemed to be “culturally similar” and often originating from wealthier countries are less likely targets of value-based threat rhetoric.

Disease threat, in turn, appears to combine both realistic and symbolic threat dimensions. From an evolutionary point of view, protection from disease through the avoidance of potential pathogens and parasites is a functional and adaptive strategy (Schaller, 2006; Petersen, Chapter 7, this volume). Throughout history, however, diseases have been associated with supposedly inferior or “dirty” outgroups and foreign populations (Joffe & Staerkle, 2007), which explains why perceptions of disease threat are related to anti-immigration attitudes (Faulkner et al., 2004; Green et al., 2010). The recent closing of national borders due to the COVID-19 pandemic raised concerns that the fear of the pandemic would fuel restrictive immigration attitudes; in the United States, for example, perceived COVID-19 threat has been found to relate to anti-Asian prejudice (Huo, 2020). In Turkey, perceived COVID-19 threat was simultaneously associated with negative attitudes toward Syrian refugees (through threat perceptions), and to pro-immigrant attitudes and helping intentions (through common ingroup identification) (Adam-Troian & Bagci, 2021; see van Bavel et al., 2020).

3.4. Individual or Collective Threat?

Negative outcomes of immigrant presence can be anticipated at the individual or the collective level, reflecting motivations of individual vs. collective self-interest (e.g., Burns & Gimpel, 2000; Citrin et al., 1997; Sears & Kinder, 1985; Stephan et al., 2016; Valentino et al., 2019). Individual threat perceptions describe situations where members of the receiving society are concerned that their individual interests are menaced by immigration. Collective threat perceptions refer to conditions where the ingroup as a whole—be it national, ethnic, or regional—is seen as threatened by immigration.

As immigrants often occupy low-status positions, low-status majority members are more likely to be confronted with immigrants than high-status members. Low-status members are therefore also more likely to view themselves in competition for similar resources such as affordable housing and jobs, and thus to perceive material threat. Indeed, the relationship between low social positions and negative immigration and cultural diversity attitudes has been amply demonstrated (Carvacho et al., 2013; Hainmueller & Hiscox, 2007; Scheepers et al., 2002; for an overview, Ceobanu & Escandell, 2010; Hainmueller & Hopkins, 2014). Similarly, low-status ethnic minorities such as Blacks and Hispanics in the United States are more likely to view themselves in competition with immigrants and thus to be more opposed to immigration (Burns & Gimpel, 2000; see however Citrin & Sears, 2014).

However, competition is not the sole explanation for the links between social status, threat perceptions, and anti-immigrant prejudice. Alternative explanations of status differences in the expression of anti-immigration prejudice highlight high-status groups’

greater awareness of anti-discrimination norms and more subtle expressions of prejudice (Jackman & Muha, 1984; Hainmueller & Hiscox, 2007; Hainmueller & Hopkins, 2014). Yet another explanation is that the effects of social status are due to differential political socialization experiences at home and at school rather than status per se (see Cavaille & Marshall, 2019; Sears & Funk, 1991; Lancee & Sarrasin, 2015, for selection effects).

With respect to collective self-interest, Citrin and colleagues (2001) have shown that although personal economic circumstances played little role in support for reducing immigration, pessimism about the national economy and beliefs about negative labor market consequences of immigration predicted anti-immigration attitudes (see also Burns & Gimpel, 2000; Stephan et al., 2016). While people who see their national ingroup as relatively *disadvantaged* in comparison with immigrant outgroups have been shown to display stronger anti-immigrant attitudes (Pettigrew et al., 2008), somewhat paradoxically, this was also the case for those who see their ingroup as relatively *advantaged* in relation to immigrant outgroups (Guimond & Dambrun, 2002). In this latter case, anti-immigrant prejudice is interpreted as a strategy to maintain the privileges of the high-status ingroup and status quo (see Jetten, 2019). Yet, in general, highly skilled immigrants are preferred over lower-skilled immigrants (Valentino et al., 2019), especially by national majority groups (Gale & Staerklé, 2021).

3.5. Threat Rhetoric

Many studies have used fictitious newspaper articles, editorials, and research findings as well as policy framings to induce threat perceptions, thereby simulating dissemination of threat-based arguments in the media and the public sphere (Esses et al., 1998; see Rios et al. 2018, for an overview). The differential impact of threat rhetoric as a function of the targeted immigrant group is demonstrated in a study showing that news reports on Latino immigrants emphasizing the costs of immigration (i.e., material threat) instead of its benefits led White US citizens to support reduction of immigration, to prefer English-only laws, and to request information from anti-immigration groups. This was far less the case when European immigrants were featured in the reports (Brader et al., 2008). Similarly, fictitious editorials depicting a highly skilled immigrant group (rather than a vaguely described immigrant group) arriving in a context where jobs are scarce evoked perceptions of competition and resulted in generalized negative attitudes toward immigrants in Canada (Esses et al., 1998). In actual political discourse, arguments put forward by British political leaders regarding Brexit leveraged both on supposed realistic (e.g., terrorism, crime, competition for jobs) and symbolic threats (e.g., value differences; Portice & Reicher, 2018). Content analyses of television news in Flanders (the northern part of Belgium) over a period of 11 years revealed that cultural and safety threats were prevalent in TV news stories regarding North African immigrants (Van der Linden & Jacobs, 2017). An Austrian study examining the effects of populist advertising found that both value (“*Respect for our culture instead of false tolerance*”) and material threat appeals (“*Protection for our jobs instead of competition and loss of workplaces*”), combined with anti-immigrant visuals (print ads for the right-wing Austrian Freedom Party depicting Muslim immigrants crossing the Austrian borders), increased feelings of symbolic threat, intergroup anxiety and negative stereotypes, and ultimately led to stronger anti-immigration attitudes (Schmuck & Matthes, 2017).

3.6. Group Identification and Threat

Because immigrants are often perceived and constructed as threatening historically developed *national* values, national identification plays an important role in anti-immigrant attitudes. Research has shown that ethnic majorities within countries are more likely to see themselves as legitimate representatives of the nation and are therefore more likely to identify with the nation (Devos & Banaji, 2005; Staerklé et al., 2010). This ingroup identification makes members sensitive to matters that may harm the group; therefore, individuals who identify strongly with their country are likely to be more concerned about the national interest than less identified individuals. Accordingly, national identification has been shown to be an antecedent of more intense feelings of threat (e.g., Riek et al., 2006). Threat triggers a motivation to defend the identity of the nation that may lead more strongly identified individuals to hold more negative attitudes toward immigrants (e.g., Blank & Schmidt, 2003; Esses et al., 2005; Mummendey et al., 2001; see Huddy, Chapter 21, this volume). Examining attitudes of Dutch adolescents, Velasco González and colleagues (2008) showed that national identification increased anti-Muslim prejudice, but this relationship was fully mediated by perceived symbolic threat (see also Bilali et al., 2018, for a similar pattern with national identification of Turks predicting negative attitudes toward Kurds through threat perceptions).

Religious identification has also been related to negative outgroup attitudes. While the research focus is generally on national majorities in Western countries, Obaidi and colleagues (2018) showed that high identification as Christians as well as Muslims in Europe, Afghanistan, and Turkey was related to greater perceived symbolic threat, and consequently to stronger outgroup hostility. National, religious, and ethnic identification may also influence the way individuals react to threat, by strengthening the link between perceived threats and hostile outgroup attitudes (Stephan et al., 2016). For example, in the US presidential campaign in 2016, exposure to messages anticipating a racial shift increased Whites' support for anti-immigrant policies and for Donald Trump, and decreased support for Bernie Sanders through heightened group status threat (Major et al., 2018). However, this pattern was only found among Whites highest in identification with Whites as a group.

Not only the degree of group attachment determines increase of anti-immigration attitudes, but also its form and content. While an uncritical and idealizing attachment to the nation based on a sense of national superiority positively relates to anti-immigration attitudes, the relationship may be negative when attachment implies pride in the nation without intergroup comparisons (Blank & Schmidt, 2003; Green et al., 2011; Grigoryan & Ponizovskiy, 2018; Mummendey et al., 2001; see also Yoogeswaran & Dasgupta, 2014). Falomir-Pichastor and Frederic (2013), in turn, showed that heterogeneous conceptions of national identity were related to perceived threat and anti-immigrant prejudice, but only among high national identifiers. Thus, it may not be identification per se that drives anti-immigration stances, but rather the meaning individuals and groups attribute to identity (Reicher & Hopkins, 2001). For example, some research has shown that national identification was related to prejudice toward asylum seekers in England only to the extent that people endorsed an ethnic conception of the nation, based on ancestry and blood ties (Pehrson et al., 2009a; see also Meeus et al., 2010). In a study highlighting the importance of representations of national history, the experimentally emphasized Christian roots of

Dutch nationhood led low national identifiers to oppose rights of Muslim immigrants to the same extent as did high identifiers (Smeekes et al., 2011).

3.7. Conclusion

In this section, we have reviewed the notion of threat and its links to immigration-related attitudes. A potentially confusing issue is the varying use of threat as an explanatory variable in immigration attitude research. Threat has been conceived as a component of prejudice and as an antecedent, as a mediator and as a moderator of the psychological processes underlying anti-immigration stances. In survey research, for example, threat perceptions are typically assessed by explicitly asking respondents the extent to which they feel immigrants threaten values or job opportunities of the national majority. These threat measures are subsequently used to predict anti-immigrant prejudice. Strong semantic overlap between threat and prejudice measures, however, could imply that threat is simply a variant of prejudice (e.g., Sniderman et al., 2004). If reverse causality cannot be excluded, such cross-sectional survey research is therefore at risk of being tautological.

The variety of methods used to study the role of threat in anti-immigration attitudes makes it indeed difficult to establish an unequivocal causal order between threat and prejudice. While experimental research (simulating threat via fictitious newspaper articles, editorials, research findings, or policy framings) addresses these critiques by manipulating threat perceptions in various ways (see Rios et al., 2018, for an overview), controlled experiments remain artificial—frequently using student populations—and thus cannot conclusively show the conditions under which threat shapes immigration policy attitudes among the general population in the real world.

Hence, the links between threat and an anti-immigrant stance may be circular. For example, people expressing anti-immigration prejudice might subsequently appeal to threat as a means to justify their prejudices (Bahns, 2017). Similarly, overestimating the size of an immigrant group in a country may be a consequence, rather than a cause, of attitudes toward those groups (Hopkins et al., 2019). The threat—prejudice circularity is also revealed in a study where immigration anxiety was related to seeking out, recalling, and agreeing with news reporting conveying threatening information regarding immigration (Gadarian & Albertson, 2014). Finally, given the widespread presence of threat rhetoric in the public sphere, perceived threat may also reflect endorsement of threat-based political discourse.

While any one method alone does not permit unequivocal causal interpretation of the threat-prejudice nexus, the increase of survey experiments embedded in large-scale social surveys can make the best of both worlds (Ford & Mellon, 2020). Yet, despite their differences in the underlying assumptions and the forms of threats they investigate, the various theories converge in viewing threat as closely related to anti-immigration attitudes.

4. CONTEXTUAL ANALYSES OF IMMIGRATION ATTITUDES

In this fourth part, we overview research examining the multiple impacts of contextual (e.g., national, regional, local) determinants on attitudes related to immigration and

multiculturalism. This more recent body of research demonstrates that the wider socio-cultural and political environment shapes individual immigration attitudes, and that these processes vary over time and across geographic and institutional contexts. The development of high quality international social surveys, such as the *European Social Survey* (ESS; see Heath et al., 2020), the *International Social Survey Programme* (ISSP), and the *World Values Survey* (WVS) has fostered comparative cross-national and cross-regional research that relates contextual factors to individual-level processes and outcomes. The basic rationale for such investigations is that individuals' attitudes toward immigration and multiculturalism are contingent upon the surrounding social contexts in which they develop, over and above individual-level determinants such as threat perceptions, intergroup contact, and ideological orientations (Christ et al., 2017; Pettigrew, 2018). Though the call for integration of different levels of analysis is far from new (Doise, 1986), the necessary multi-level research designs to do so have become common only over the last two decades, as they can now be readily implemented with a number of software packages. Multilevel approaches allow the simultaneous examination of different levels of analysis by combining individual-level predictors with national- or regional-level factors in a single explanatory model (e.g., Hox, 2010). In statistical terminology, the data is hierarchically organized in a multilevel data structure where individuals are nested within one or more higher-level contextual units. Thus, psychological explanations of public opinion toward immigration and immigrants can be complemented with structural, political, historical, and institutional explanations.

The contextual units can be *distal*, such as nations or regions, or more *proximal*, such as districts, neighborhoods, schools, or even classrooms. In early multilevel research, the conceptualization of contextual units has mainly relied on intergroup competition and intergroup contact (see Christ et al., 2022, for an overview). The two most commonly studied context-level characteristics relate to national economic conditions (e.g., GDP, unemployment rate) and to national immigration and ethnic diversity patterns (e.g., proportion of immigrants, change in immigrant proportion, ethnic fractionalization) that provide information on the structural and compositional dimensions of the contexts in which individuals develop their attitudes toward immigration and cultural diversity. More recent research has furthermore examined the impact of ideological and normative contexts (e.g., policies, surrounding public opinion) on citizens' views regarding immigration (Guimond et al., 2014). This research has offered innovative approaches to further our understanding of the processes underlying the context–attitude relationship (mediating processes) and demonstrated key boundary conditions of such processes (moderating processes). In the following, we overview and discuss these different bodies of research.

4.1. Extending Threat and Contact Approaches to a Contextual Level

Drawing on both realistic conflict theory and social identity theory, Scheepers and colleagues (2002) were among the first to theorize and empirically assess threat as a context-level factor in a multi-level perspective, formalized in *ethnic competition theory* (see also Blalock, 1967; Quillian, 1995; see Section 3 of this chapter). On the individual level, ethnic competition theory defines competition in terms of the social conditions (e.g., professional category, income) of members of the receiving society: low-status conditions may elicit perceptions of a competitive relationship with immigrants that in turn may give rise to

anti-immigration sentiments. Competition on the contextual level, in turn, is assessed with the economic conditions of a country or a region, assumed to affect competition between members of the receiving society and immigrants. The reasoning is that in a disadvantaged context—indexed by high unemployment rates for example—competition for scarce resources such as jobs is likely to be greater than in an advantaged context (see also Green, 2009; Kunovich, 2004; Kunst et al., 2017; Quillian, 1995).

Group (or “fraternal,” Runciman, 1966) relative deprivation—understood as a perceived group-level disadvantage in relation to other groups resulting in a sense of ingroup entitlement—is known as a powerful driver of anti-immigrant prejudice (see Smith et al., 2012). Recently, Meuleman et al. (2020) found across 20 European countries that national-level long-term unemployment was not directly related to perceived threat, but that group relative deprivation was higher in high-unemployment countries. Group relative deprivation, in turn, was related to perceived threat. This finding suggests that group relative deprivation explains (i.e., mediates) how disadvantageous labor market conditions translate into anti-immigration attitudes.

One of the key recent debates has been whether ethnic diversity resulting from a growing number of immigrants erodes social cohesion and triggers anti-immigrant sentiments (the constrict hypothesis, as discussed in section one, Putnam, 2007), or alternatively fosters more inclusive immigration attitudes. Two contrasting rationales—one extending competition frameworks and the other one intergroup contact theory—have been put forward to examine how migration patterns shape immigration attitudes and political behavior (see Christ et al., 2022). In the following, we overview evidence for both rationales and conclude by discussing potential explanations for contradictory and mixed evidence.

Threatening diversity. The threat approach suggests that a high or growing proportion of immigrants elicits both perceived material and value threats. In this view, greater exposure to immigrants increases perceived economic competition (material threat) and reinforces sentiments of alleged challenges to national values and lifestyle (value threat). Across 15 European countries, Scheepers and colleagues (2002) showed that individuals living in similar conditions as immigrants were more likely to endorse threat perceptions, and that a strong presence of non-EU citizens within a country was directly related to ethnic exclusionism (assessed with opposition to the granting of civil and social rights to immigrants). Comparing measures of immigrant presence, another study showed that while the percentage of low-status immigrants in European countries did not affect individual threat perceptions, a higher percentage of non-Western immigrants was associated with greater country average levels of perceived immigration threat (Schneider, 2008; see Green et al., 2010). Rink et al. (2009), in turn, found, over time across three electoral surveys, that the proportion of immigrants in a municipality was positively related to voting for the Vlaams Belang (a nationalist, right-wing populist party) in Flanders, Belgium.

Contextual diversity can also interact with other factors. In an early multilevel study, Quillian (1995) showed that while higher proportions of immigrants from non-European countries was associated with greater racial prejudice, this relationship was more likely to occur in countries with poor economic conditions (see also Green et al., 2018). Individual-level factors such as ideological orientations further moderate the effects of context-level diversity. For example, Van Assche and colleagues (2014, 2016) found that a higher proportion of ethnic minorities was most closely associated with greater prejudice and outgroup

distrust among individuals high in RWA (see also Sibley et al., 2013, for the moderating effect of dangerous world beliefs).

The threat approach has also been applied to examine the impact of temporal contexts, demonstrating that *changes* in immigration and economic conditions may affect perceived competition. Pooling Dutch surveys over 1979–2002, Coenders and colleagues (2008, study 1) showed that ethnic discrimination was more widespread in times of high levels of immigration and increased unemployment. Moreover, birth cohorts having experienced high immigration and unemployment levels in their formative pre-adult years expressed greater ethnic discrimination. Similar patterns were found across European countries in an examination of a narrower time frame from 2002 to 2007 (Meuleman et al., 2009). This study showed that countries with weaker inflows of immigrants had more tolerant immigration attitudes than those with higher levels of immigration, and that attitudes toward immigration became more tolerant particularly in countries where unemployment rates did not increase. In a natural experiment in the Greek islands, Hangartner and colleagues (2019) recently revealed that large and sudden direct exposure to refugees increased natives' hostility toward refugees and support for restrictive immigration and asylum policies.

Diversity as an opportunity. Predictions derived from extensions of intergroup contact theory (Tropp and Dehrone, Chapter 29, this volume), however, are at odds with those derived from threat and competition perspectives: contact theorists have established that living in culturally diverse societal contexts (i.e., with a high proportion of immigrants) provides more contact opportunities, notably through intergroup friendships that decrease rather than increase perceived threat and antagonistic attitudes toward immigrants (Hewstone, 2015; Wagner et al., 2006). The proportion of immigrants within German districts (intermediate administrative levels between states and municipalities), for example, has been shown to be negatively related to immigrant prejudice, and this relationship was mediated by contact at the workplace and in neighborhoods (Wagner et al., 2006). In another study focusing on both the White British majority and ethnic minorities in the United Kingdom, Schmid and colleagues (2014) found that *neighborhood* ethnic diversity was associated with greater intergroup contact. This intergroup contact was related to lower threat perceptions that in turn resulted in higher outgroup, ingroup, and neighborhood trust, respectively, as well as in more positive intergroup attitudes. Across European countries, Schlueter and colleagues (2020) similarly found that higher proportions of Muslims in a country were associated with more positive attitudes toward Muslim immigrants. These results are at odds with Putnam's (2007) "constrict claim" according to which neighborhood diversity erodes social cohesion, especially because these positive effects have been found to hold also for the presence of stigmatized immigrants in neighborhoods.

Reconciling contact and threat rationales. Although diversity-based threat and intergroup contact processes appear to contradict each other, it is likely they operate *simultaneously* in explaining the relationship between diversity and immigration-related attitudes and political behavior. For example, Schlueter and Wagner (2008) demonstrated that a greater regional proportion of immigrant populations in Europe increased both intergroup contact *and* perceived threat. Subsequently, Pettigrew and colleagues (2010) showed that the effect of contact is based on direct *experience* with immigrants and is thus affected by

the actual size of immigrant populations within German regions, whereas perceived threat is triggered by the *perception* of immigrant presence (see also Hooghe & Vroome, 2015a; van Assche et al., 2016). Green and colleagues (2010) in turn found that the presence of western European migrants was related to increased intergroup contact in Swiss municipalities, which in turn was linked to reduced threat perceptions. The presence of stigmatized migrants (mainly from Turkey, Albania, and countries of former Yugoslavia), however, was related to both increased intergroup contact and threat perceptions. Extending this study to political behavior in Switzerland, Green and colleagues (2016) showed that the presence of stigmatized immigrants at the district level was related to threat perceptions, but not to intergroup contact. District-level perceived threat, in turn, was related to actual radical right-wing voting through an increased willingness to vote for right-wing parties. Positive intergroup contact, however, was associated with less radical right-wing voting through lower willingness to vote for right-wing parties and reduced threat. Finally, Laurence and colleagues (2018) showed that neighborhood and workplace ethnic diversity were related to both positive and negative intergroup contact experiences that further relate to positive and negative intergroup attitudes, respectively.

Other studies have also shown the *interplay* between threat and intergroup contact processes. In a study across 17 European countries, McLaren (2003) revealed that while a high proportion of foreigners in a country increases perceived threat, immigrant friendships buffer this effect, suggesting that individuals with immigrant friends living in highly diverse contexts feel less threatened by diversity than those without such friendships. Similarly, the proportion of foreign-born in US regions had less impact on Whites' immigration attitudes when their interpersonal networks included non-White members (Berg, 2009; see also Laurence, 2014, for a similar pattern in the United Kingdom). Moreover, the proportion of immigrants in European countries has been shown to moderate the relationship between intergroup contact and anti-immigrant prejudice (Semyonov & Glickman, 2009). Positive contact was related to less negative attitudes toward immigrants to a greater degree in countries with a large number of non-Europeans, compared to countries with a smaller number of non-Europeans. Extended, indirect contact (knowing ingroup members who have immigrant friends), however, has been shown to be more effective in reducing prejudice for individuals living in segregated neighborhoods with few direct contact experiences with immigrants, compared to individuals from mixed neighborhoods with more opportunities for direct contact (Christ et al., 2010).

Navigating mixed evidence. Although predictions based on threat and contact approaches have both received much empirical support, some studies found no evidence for the role of context-level factors in explaining immigration attitudes. In a study across 20 European countries, for example, no effects were found of the economic situation and of the proportion of immigrant populations on hostile attitudes toward immigration (Sides & Citrin, 2007). In another study, no effect was found of the proportion of Muslim populations on anti-Muslim attitudes across European countries (Strabac & Listhaug, 2008). In yet another cross-European study, the proportion of Muslims in a country was positively related to perceived material threat and negatively to perceived symbolic threat, but unrelated to right-wing voting intentions (Lucassen & Lubbers, 2012). Moreover, comparing attitudes toward foreigners across different regions of Germany, Semyonov and colleagues (2004) revealed that the *actual* proportion of the immigrant populations within regions had no effects on such attitudes, whereas a high *perceived* size of immigrant

populations was associated with perceived threat and discriminatory attitudes toward foreigners (see also Craig et al., 2018). Indeed, a recent meta-analysis examining the links between diversity and prejudice conducted by Pottie-Sherman and Wilkes (2017) also revealed either positive or negative relationships, and in over half of the studies no relationship was found.

The territorial size of the contextual unit of analysis and the degree of ethnic segregation within those units may explain some of the apparent contradictions between the predictions derived from threat and contact approaches. The positive effects of intergroup contact have been shown to occur predominantly at a proximal and local level (e.g., municipality, neighborhood, or district), where daily interactions between immigrants and members of the receiving society are plausible (see Wagner et al. 2006; Schmid et al., 2008; see also Dinesen & Sønderskov, 2015). A large presence of immigrants at a distal, national level, however, may be more likely to enhance threat perceptions due to an increased political concern with immigration, reflected in widespread anti-immigrant discourse in the media. In line with this argument, a US study examining attitudes of Asian Americans, Blacks, Latinos and Whites found that interethnic diversity reduced perceived threat and prejudice at the neighborhood level but increased it at the city (“metropolitan”) level (Oliver & Wong, 2003). Similarly, Biggs and Knauss (2012) showed that in UK *neighborhoods* with greater proportions of non-Whites (South Asians and Muslims in particular), the probability of being a British National Party (BNP) member was lower among white British adults. However, this probability was higher in *cities* (a larger unit of analysis compared to neighborhoods) with a greater proportion of non-Whites, and even more so when minorities were clearly segregated (see also Ford & Goodwin, 2010). In the same vein, Laurence and colleagues (2019) showed that a high proportion of non-whites in UK neighborhoods was associated with reduced prejudice in diverse areas with low levels of segregation, whereas prejudice was heightened in segregated areas. A study across European countries also revealed that living in mixed—as opposed to homogeneous or highly ethnic—neighborhoods was linked to reduced threat perceptions and social distance toward immigrants, whereas the immigrant ratio in the country was related to increased threat perceptions (Semyonov & Glickman, 2009). Finally, a recent meta-analysis demonstrated that social trust (as an indicator for social cohesion) was reduced in ethnically diverse local, proximal levels (i.e., neighborhoods), but this effect was less marked or even reversed at a more distal level (e.g., districts) (Dinesen et al., 2020). The ideological climate reigning in a given context, which we turn to next, may be another way to shine a light on some of the contradictory and mixed effects of diversity.

4.2. Ideological Climates and Immigration Attitudes

Up to now, we have discussed how individual opinions are affected by structural and compositional features of contexts. We finish this section by examining how ideological characteristics of contexts may provide normative guidance regarding socially acceptable and desirable ways to think about and deal with immigration and cultural diversity (e.g., Guimond et al., 2014; Pettigrew, 2006, 2018). Three types of ideological climates are described: (a) *top-down* ideological climates, institutionalized through legislation and

integration policies; (b) ideological climates based on political and media discourse; and (c) *bottom-up* ideological climates based on aggregated individual-level data.

4.2.1. *Integration Policies as Ideological Climates*

Several studies have used national integration policies as indicators of positive institutionalized norms that may signal to both immigrants and natives that cultural diversity is valued and that immigrants are treated in fair and welcoming ways. In a study across four countries, Guimond and colleagues (2013) showed that national integration *policies* were linked to perceived integration *norms* of citizens of these countries, which in turn predicted their *attitudes* toward immigrants. In a cross-European study, Schlueter and colleagues (2013) found that inclusive integration policies (as measured by the *Migrant Integration Policy Index*, Niessen, 2009) were related to reduced threat perceptions (see also Callens & Meuleman, 2016; Hooghe & Vroome, 2015b). Likewise, Green and colleagues (2020) showed that inclusive integration policies, at the national level, were related to lower levels of symbolic threat perceptions and to more extensive intergroup contact. Inclusive integration policies further reinforced the negative relationship between contact and threat perceptions (see also Kende et al., 2018, for a similar pattern for countries endorsing egalitarian as opposed to hierarchical values). In yet another cross-European study, Schlueter and colleagues (2020) found that inclusive immigrant integration policies, and to some degree stronger state support for religious practices, were associated with less negativity toward Muslim immigrants. These studies thus suggest that citizens are at least to some extent aware of and influenced by the surrounding policy contexts that guide citizens' views on immigration.

Recent research further revealed that the mixed effects of diversity may also be due to the interaction between immigrant integration policies and immigrant presence. Kende and colleagues (2022) found that across national, regional, and institutional (i.e., school) levels of governance, anti-immigrant prejudice was lower when immigrant presence was coupled with inclusive policies that render immigrants more equal to natives. National policy contexts have also been found to moderate the relationship between ideological beliefs and immigration attitudes. In a cross-European study, Kauff and colleagues (2013) found that the relationship between right-wing authoritarianism and negative diversity beliefs was stronger in more inclusive countries, suggesting that a multicultural ideology and inclusive policies may pose a threat to authoritarian individuals.

4.2.2. *Political and Media Discourse as Ideological Climates*

The positions of political parties on cultural diversity and immigration are other normative reference points that shape citizens' opinions. Accordingly, the relative strength of political parties within a given context is another indicator of the ideological climate of countries. A strong presence of right-wing parties, for example, has been shown to increase anti-foreigner sentiment across European countries, over and above individuals' political orientation (Semyonov et al., 2006; see also Lahav, 2004). Yet, the picture is more complex as specific ideological emphases in political party discourse moderate their impact on individuals' attitudes: the presence of extremist parties promoting blatant racism

(based on *biological* intergroup differences) did not affect public opinion as a whole, since such views have become increasingly socially unacceptable. Instead, the national prevalence of right-wing parties with a culturalist racist agenda (based on essential *cultural* differences) was shown to relate to anti-immigrant attitudes (Wilkes et al., 2007). Examining the role of media reports as contextual sources of perceived threat, Schlueter and Davidov (2013) showed that negative immigration news reporting shapes national majorities' threat perceptions regarding immigration. Linking repeated cross-sectional survey data from Spain with regional statistics on immigrant presence and a longitudinal content analysis of news reports, they found that negative immigration reporting was related to increased threat perceptions, but this relationship was weaker in regions where the presence of immigrants was higher. These findings suggest that opportunities for contact can buffer the pernicious consequences of negative media portrayals regarding immigration.

4.2.3. *Bottom-Up Ideological Climates*

Shared ideological beliefs and values as well as aggregated individual expressions regarding immigration within a given context may be seen as *bottom-up* normative climates (Green & Sarrasin, 2019). Much like policies, these shared ideological beliefs are also broadly situated on a continuum from exclusionary to inclusive. For example, a study using Swiss national referenda results at the level of municipalities provided an indicator of local ideological climates based on actual voting behavior of citizens on a wide range of social issues (Sarrasin et al., 2012). This study evidenced stronger opposition to liberal anti-racism laws in municipalities with conservative, exclusionary ideological climates, after accounting for individual-level ideological orientations. Right-wing ideological climates across countries and regions have further been shown to moderate the relationship between individual right-wing ideologies and negative immigrant attitudes (as well as other outgroup attitudes; see van Assche et al., 2016): in strong right-wing oriented climates, individual outgroup attitudes converge toward prejudice, regardless of personal ideology.

Ethnic and civic conceptions of national citizenship, finally, make up ideological climates at both the top-down policy level and the bottom-up individual level of shared values in national populations. Across 15 European countries, Weldon (2006) showed that residents in countries with *ethnic* citizenship regimes—requiring shared ethnicity and ancestry for citizenship—were less willing to grant political rights to ethnic minorities compared to residents in countries with *civic* citizenship regimes (i.e., assimilationist and pluralistic regimes). Individuals in assimilationist regimes, in turn, were less tolerant than individuals in pluralistic regimes. Another study revealed lower levels of anti-immigrant prejudice in countries with a collective representation of *civic* nationhood. Moreover, the relationship between national identification and anti-immigrant prejudice was weaker in these countries, suggesting that national identification defined by shared civic citizenship is less related to the desire to exclude immigrants (Pehrson et al., 2009b).

This brief overview suggests that ideological climates—be they defined by top-down institutional factors or by bottom-up shared representations—may offer citizens a normative framework of reference on which they rely when making up their minds on immigration and cultural diversity.

4.3. Future Avenues for Contextual Research

Contextual-level analyses in political psychology have contributed to the understanding of how local, regional, national, and also temporal contexts affect individual opinions regarding immigration. Though in recent years the processes that account for the relationship between context and attitude have been thoroughly examined, there is still a need for more systematic and more nuanced theorizing of these mechanisms occurring at different contextual levels, for example by using varying indicators of ideological climates and multiple outcome variables.

An important issue to consider in analyzing the impact of proximal contexts (such as neighborhoods) is the role of self-selection. Indeed, it is possible that a link between immigrant ratio in a given context and more positive immigrant attitudes results from tolerant individuals self-selecting into diverse areas and, conversely, less tolerant individuals leaving these areas. For example, Maxwell (2019) found with Swiss panel data evidence that individuals holding pro-immigrant attitudes moved into urban, typically more ethnically diverse areas, but that individuals with anti-immigrant attitudes were not moving out of such urban areas. Using longitudinal data from England and Wales, Kauffmann and Harris (2015), however, found no evidence for the role of self-selection in explaining the more positive immigration attitudes among British Whites in more diverse local contexts.

One must also acknowledge that the bulk of this strand of research examines majority attitudes in receiving countries in the Global North. Indeed, immigrant minorities are under- or misrepresented in national surveys (e.g., Feskens et al., 2006). As a result, multi-level research focusing on the immigrant minority perspective remain scarce (for exceptions, see Schmid et al., 2014; Staerklé et al., 2010). For example, Kauff and colleagues (2016) revealed that national minority members were more likely to support anti-discrimination laws and immigrant rights in social contexts in which majority members had experienced positive intergroup contact. This finding counters the concern that positive intergroup contact may demobilize minorities (Tropp and Dehrone, Chapter 29, this volume). Politi and colleagues (2022), in turn, showed that inclusive integration policies were related to migrants' naturalisation intentions and to the endorsement of integration as an acculturation strategy.

Examining how contextual factors shape immigrant minority experiences and attitudes as well as the interplay between majority and minority perspectives is essential for bringing the field forward. The omission of research on the Global South, in turn, is mainly due to the lower coverage of such countries in large-scale social surveys. Insofar as contextual factors driving attitudes toward migration may differ drastically between the Global North and South, sampling of countries in international social surveys should be extended, and scientific and structural collaborations between regional social surveys should be promoted.

5. CONCLUSION

This chapter proposed an overview of research on migration and multiculturalism from the perspective of political psychology. We started our discussion with a historical framing of the two major modes of migrant incorporation: assimilation and multiculturalism. In the

second section, we presented research studying the perspective of migrant groups, showing the interactionist nature and the complexity of contemporary migrant identities as well as the pros and cons of various acculturation strategies employed by migrants. We also highlighted the intergroup nature of attitudes toward multiculturalism and of acculturation strategies between national majorities and ethnic migrant minorities. In the third section, we focused on research investigating the role of various forms of perceived threat associated with migrant groups by national majorities. The final section featured recent multilevel research on majority attitudes toward migration across national and regional contexts.

An important goal of the chapter was to relate the principles of assimilation and multiculturalism to the dialectic processes of intergroup similarity and differentiation, respectively. The research reviewed clearly indicates that migrant experiences, and reactions to immigration by receiving societies, express the complex and dynamic interplay of similarity and difference, at the level of motivations, perceptions, and normative expectations. For migrant groups, qualified and selective *similarity* with the receiving society's majority is an asset for a successful migrant experience, for example through language acquisition and awareness of dominant social norms. At the same time, intergroup *difference* and concomitant identification with their ethnic group is likely to help many migrants to construct positive social identities rooted in the everyday experiences and practices associated with their ethnic group. Importantly, research has also emphasized that such differentiation processes do not only operate *between* migrant groups and receiving majorities, but also *within* migrant categories, in particular between early and recent migrants; between first-, second-, and third generation migrants; between migrant organizations defending contrasting visions of incorporation; and between different ethnic groups.

Yet, the demands and practical implications derived from the principle of intergroup similarity may be contradictory: majorities may expect migrants to "adapt" and respect "their values," but when they do so, they may become threatening competitors for jobs and other material resources of the majority group. Intergroup difference can be equally paradoxical: migrants who are portrayed as (too) different from the majority culture allegedly threaten social cohesion and national values. At the same time, majorities may prefer that migrant groups, especially those they dislike, remain apart from them in order to safeguard an imaginary homogeneity of their ingroup. Intergroup difference is furthermore enhanced through majority practices that make integration more difficult, such as unequal treatment by authorities, lack of institutional support for integration, widespread discrimination, or segregated housing. Research therefore needs to carefully spell out the specific meaning and practical implications of intergroup similarity and difference that is implied by political rhetoric and hidden in general attitudes toward immigrants. Research should also more clearly differentiate attitude formation toward contrasting types of immigrants, for example by comparing attitudes toward high- versus low-status immigrants, or toward immigrants from culturally similar versus distant countries. Currently, to maximize cross-national comparability, large international surveys mainly refer to generic immigrants in their item wording. However, additionally assessing attitudes toward immigrants of specific national origin—that may vary from country to country—would allow to paint a more accurate picture of the psychological processes involved in immigration attitude construction.

During the last two decades, migration and multiculturalism have become one of the most heavily debated issues in contemporary receiving societies, both at the level of political discourse and in everyday conversations. As illustrated in studies on migrant identity

construction and ideological climates reviewed in this chapter, this societal communication is likely to affect the way citizens think about immigrants. Politicians, migrant group leaders, members of the civil society and other “identity entrepreneurs” (Reicher & Hopkins, 2001) participate in the societal immigration debate by strategically communicating specific understandings of assimilation and multiculturalism. In this view, for example, “threat perceptions” are the outcome of social influence processes that deliberately portray certain migrant groups as “different” or “dangerous.” These discourses participate in the construction and diffusion of positive and negative meanings of migration, thereby creating socially acceptable, and often simplified, ways of thinking and talking about immigrants and immigration. In future research, political psychology could gain from placing a stronger emphasis on the implications of this ongoing communicative process on how migrants construct their ethnic identities and how majorities ascribe characteristics on migrant groups.

Finally, the variety of methodological and theoretical approaches through which political psychology has studied phenomena of migration and multiculturalism is an important asset for making our research relevant to policy makers and practitioners (see Esses et al., 2017; Wills, 2010). Discursive, experimental, and survey research have different stories to tell about migration and immigration. Yet, despite their often conflicting theoretical assumptions, we hope and assume they share the normative goal of making our multicultural societies more inclusive and a better place to live for all citizens. Researchers in political psychology should therefore highlight the implications of their studies on migration and immigration policies. As we have shown in this chapter, political psychology has a great deal to offer to promote the chances for successful migrant experiences as well as positive, enriching, and constructive relationships between migrant groups and national majorities.

NOTE

1. Throughout the chapter we use the term “receiving society” instead of “host society” in order to avoid connotations of migrants being passively “hosted” by national majorities. The term “migrant” is used when migration is analyzed from the perspective of those who move into new contexts, while the term “immigrant” is employed to describe the perspective of the receiving society into which migrants immigrate.

CHAPTER 29

PREJUDICE REDUCTION AND SOCIAL CHANGE

Dual Goals to Be Pursued in Tandem

LINDA R. TROPP AND TRISHA A. DEHRONE

RECENT theorizing in social and political psychology suggests that intergroup relations may be construed either in terms of efforts to achieve prejudice reduction and intergroup harmony, or to achieve social change to promote intergroup equality, with the expectation that these goals are inherently in opposition to each other (e.g., Dixon et al., 2012; Cikara & Paluck, 2013). In this chapter, we contend that promoting prejudice reduction at the relational level, and social change toward equality at the societal level, may be conceived of as dual goals to be pursued in tandem, rather than necessarily being framed as goals in conflict. With this lens, we review a number of theoretical perspectives on prejudice reduction and social change, including literature on intergroup contact, common group identities, and social norms. Throughout the chapter, we stress how a dual focus on prejudice reduction and social change can inform our understanding of relational and structural challenges in intergroup relations, with special attention to the integral role that group status plays in shaping people's perspectives and experiences in relation to other groups (e.g., Dovidio et al., 2009; Jones & Dovidio, 2018; Tropp, 2006). We conclude the chapter with suggestions for integrative research that may be pursued to fill gaps in the existing literature, along with discussing implications of such work for interventions that seek to reduce prejudice and promote social equality.

1. PREJUDICE REDUCTION

Long-standing pursuits in the intergroup research literature have been to specify the nature of prejudice (Allport, 1954; Dovidio et al., 2005), along with identifying the individual and societal factors that contribute to and maintain prejudice (Duckitt, 1992; Kinder, Chapter 27, this volume; Zanna & Olson, 1994), and possible strategies through which prejudice between groups might be reduced (Paluck et al., 2021; Tropp & Molina, 2019). Since its early origins, scholarly writings on prejudice have emphasized ways in which people

harbor distinctions between members of their own group and other groups (e.g., Sumner, 1906; Tajfel, 1981), and how they typically reserve more positive attitudes, more generous attributions and associations, and greater resources for members of their own group relative to those granted to members of other groups (e.g., Brewer, 1999; Cikara et al., 2014; Greenwald & Pettigrew, 2014; Tajfel & Turner, 1979).

Along with this historical emphasis, the focus of scholarship on prejudice and prejudice reduction has shifted considerably over the last several decades, both in terms of the perspectives of people studied, and in terms of how this social problem can and should be addressed. Early studies of prejudice and prejudice reduction typically centered on the perspectives of dominant groups (see Shelton, 2000; Swim & Stangor, 1998; Tropp & Pettigrew, 2005b), highlighting the prejudices of those who held more privileged positions in society toward groups who were disadvantaged or marginalized, in order to consider strategies by which their prejudices might be reduced (see, e.g., Allport, 1954; Pettigrew, 1998; Kinder, Chapter 27, this volume). One outgrowth of this tendency was for members of disadvantaged groups to be seen as little more than “objects” of others’ attitudes (Amir, 1969; Jones et al., 1984; Shelton, 2000), an unfortunate tendency that persisted even as researchers began to investigate prejudice from the perspectives of members of disadvantaged and marginalized groups toward the end of the 20th century. Throughout the 1980s and 1990s, for instance, a proliferation of research focused on the perspectives of “targets” of prejudice (see, e.g., Jones et al., 1984; Swim & Stangor, 1998), with a particular emphasis on understanding the effects of being targeted by prejudice and discrimination for psychological well-being (e.g., Crocker & Major, 1989), thereby inadvertently relegating the experiences of disadvantaged groups to being “nothing more than reactions to oppression” (Jones et al., 1984, p. 180). Only since the dawning of the new millennium—and with fresh insights afforded by the greater racial and ethnic diversity of scholars in the field—has research begun to incorporate more fully the perspectives and experiences of minoritized groups into studies that examine the foundations of intergroup prejudice (e.g., Monteith & Spicer, 2000) and how members of dominant and minoritized groups relate to and form attitudes toward each other (e.g., Devine & Vasquez, 1998; Perez & Vicuña, Chapter 25, this volume; Shelton, 2003; Shelton et al., 2006; Tropp, 2006).

2. PREJUDICE REDUCTION THROUGH INTERGROUP CONTACT

Among the strategies proposed to reduce prejudice and improve relations between groups, one of the oldest and most widely studied approaches involves intergroup contact (see Allport, 1954; Brown & Hewstone, 2005; Green & Staerkle, Chapter 28, this volume; Pettigrew & Tropp, 2011). In the psychology research literature, intergroup contact refers specifically to face-to-face interaction between members of distinguishable social groups; this contact may be reported by participants themselves, or observed directly in research studies (Pettigrew & Tropp, 2006). In either case, this definition of contact would not include studies that rely on proximity between groups or proportional indices reflecting local

diversity to infer that some degree of interaction between groups has occurred (see, e.g., Enos, 2014; van der Meer & Tolsma, 2014).

Whereas studies using indicators of group proportions or proximity tend to show that greater outgroup representation corresponds with greater expressions of intergroup prejudice and threat (e.g., Craig et al., 2018; Enos, 2017; Quillian, 1995), intergroup contact research typically reveals that greater contact between groups corresponds with lower levels of intergroup prejudice and threat (see Pettigrew & Tropp, 2011, for a review). Nonetheless, it has long been recognized that contact between groups may still carry the potential to heighten intergroup hostility and prejudice (Allport, 1954; Hewstone, 2003; Pettigrew & Tropp, 2011; Williams, 1947); hence, early scholarship on intergroup contact sought to specify conditions that could be instituted within the spaces where members of different groups interact to maximize the likelihood of achieving salutary outcomes from their contact. These optimal conditions—which were originally generated by Allport (1954) and Williams (1947), and later refined and consolidated by Pettigrew (1971; 2021)—include establishing equal status between groups within the contact situation, promoting cooperation between groups as they work toward common goals, and ensuring that this type of equal status, cooperative contact is supported by institutional authorities, policies, laws, and customs. Numerous research studies spanning many decades indicate that, while these conditions are not essential to achieve positive outcomes from intergroup contact, greater reductions in prejudice are likely to result when contact between groups is structured in accordance with these optimal conditions (Pettigrew & Tropp, 2006).

More recent generations of scholarship on intergroup contact have focused on analyzing the psychological processes and mechanisms through which contact contributes to prejudice reduction (see Paolini et al., 2021, for a review). Research conducted in countries around the globe indicate that more intimate forms of intergroup contact, and contact that involves positive interactions across group lines, have greater capacity to reduce prejudice, as compared to other, more distant forms of contact, or contact experienced as negative in valence (Paolini et al., 2021; Tropp et al., 2017). Longitudinal, experimental, and meta-analytic studies converge in showing that positive, close contact between groups—such as that typified by cross-group friendships—is especially likely to reduce intergroup prejudice and improve intergroup attitudes, relative to other forms of contact (Binder et al., 2009; Davies et al., 2011; Page-Gould et al., 2008; Pettigrew, 1998; Tropp & Pettigrew, 2005a). Related work reveals how pathways involving reduced feelings of intergroup threat and anxiety, and greater experiences of intergroup empathy, help to explain why intergroup contact typically contributes to prejudice reduction (Finlay & Stephan, 2000; Levin et al., 2003; Paolini et al., 2004; Pettigrew & Tropp, 2008; Swart et al., 2011).

Although research in the intergroup contact literature has tended to focus on relations between racial, ethnic, religious, and national groups (see Brown & Hewstone, 2005; Pettigrew & Tropp, 2006), a growing body of research has begun to consider the effects of contact between political groups. In light of increasing polarization and overt hostility between political partisans, particularly in the United States (see Ahler & Sood, 2018; Iyengar et al., 2012; Moore-Berg et al., 2020), a number of studies now show that greater engagement across political group lines can ease affective polarization and lessen partisan animosity (Amsalem et al., 2021; Levendusky & Stecula, 2021; Wojcieszak & Warner, 2020). Similar trends have also been observed among opinion-based groups, where sharing personal narratives and experiences relevant to one's political opinions may not only foster greater perceptions

of similarity across group lines (Wojcieszak & Warner, 2020), but may also contribute to shifting political attitudes and behavioral intentions related to social issues and policies (see, e.g., Hoskin et al., 2019; Kalla & Broockman, 2020; Röpke et al., 2019).

3. PREJUDICE REDUCTION THROUGH COMMON GROUP IDENTITIES

An alternate prejudice reduction strategy involves the introduction of a new common group identity, or enhancing the salience of an existing common group identity, that can include members of the different groups who are present in the intergroup context (see Gaertner & Dovidio, 2000, for a review). Research on this approach is informed by the legacy of scholarship on principles of social categorization, and the role that salient group memberships play in intergroup relations. Generally, this body of work would suggest the more that distinctions between groups are made salient and emphasized in the intergroup context, the more likely it is that members of distinct groups will accentuate group differences and harbor prejudices toward each other, while demonstrating more favorable evaluations and attitudes toward members of their own groups (Tajfel, 1974; Tajfel & Turner, 1986; Turner et al., 1987; Turner & Reynolds, 2012).

Growing from these original insights, intergroup researchers have long debated the role of group membership salience in prejudice reduction strategies. Some scholars have proposed that the salience of group membership should be minimized in intergroup contexts, to reduce a focus on group differences and facilitate the ability for members of distinct groups to recognize and come to know each other as differentiated individuals (i.e., *decategorization*; see Brewer & Miller, 1984; Miller, 2002). At the same time, other scholars stressed that it is necessary for group membership to be salient in intergroup contexts, so that any positive encounters or associations people have with individual members of another group will be more likely to generalize and extend to reduced prejudice toward that other group as a whole (i.e., *categorization*; see Brown & Hewstone, 2005; Hewstone & Brown, 1986).

In light of these ongoing debates regarding the role of group membership salience, Gaertner, Dovidio, and their colleagues proposed *recategorization* as a novel prejudice reduction strategy. According to their Common Ingroup Identity Model, members of distinct groups can be encouraged to recognize their shared membership in a larger, superordinate category that can include each group—thereby creating a common group identity (see Gaertner & Dovidio, 2000; Gaertner et al., 2016). Due to the same processes of social categorization that govern other forms of intergroup bias, attitudes toward former outgroup members would become then more positive, because they are now recognized as part of a common ingroup and afforded the kinds of positive evaluations and attitudes that are typically reserved for fellow ingroup members (Hogg & Abrams, 1988). Gaertner, Dovidio, and their colleagues have conducted numerous studies in laboratory and field settings showing the benefits of recategorization for reducing intergroup prejudice and improving intergroup attitudes (e.g., Gaertner & Dovidio, 2000; Gaertner et al., 1989; Gaertner et al., 1994; Nier et al., 2001; Riek et al., 2010).

Like the broader intergroup contact literature, research on common group identities has recently been extended to examine its role in regard to political polarization and ideological division. Complementing the earlier work summarized above, recent survey and experimental studies show that inter-party hostility and polarization are weakened when greater emphasis is placed on a common national group identity that can include partisans from different sides of the American political spectrum (see Iyengar et al., 2019; Levendusky, 2018; Warner et al., 2020). Likewise, related studies from Chile and Northern Ireland also suggest that a common national group identity can foster greater empathy and forgiveness between opposing political groups with histories of violent conflict (Noor et al., 2008; González et al., 2011).

4. PREJUDICE REDUCTION STRATEGIES: CHALLENGES AND SHORTCOMINGS

Though prejudice reduction strategies such as intergroup contact and creating common group identities have yielded many positive outcomes, they are not without challenges and shortcomings. One set of challenges involves the tendency for people to prefer surrounding themselves with similar others (McPherson et al., 2001), and to avoid diverse settings or interactions with diverse others that are often associated with feelings of discomfort, threat, or anxiety (Plant & Devine, 2003; Shelton & Richeson, 2005). Indeed, people often self-select into communities where they share relevant commonalities with others, thereby distancing themselves from people and groups who have largely different perspectives and experiences in society (Iyengar et al., 2019; Krysan et al., 2009; Kye, 2018; Turner et al., 2021; Van der Laan Bouma-Doff, 2007). Compounding these individual choices, entrenched patterns of societal inequality and racial and economic segregation further divide social groups in terms of the degree to which they can relate to each other's lived experiences (Massey, 2016; Rothstein, 2017). Together, these relational and structural factors both create considerable obstacles to the prospect of achieving reductions in prejudice and more positive attitudes and relations between groups.

In light of deeply rooted social divisions due to segregation and inequality, several scholars have also questioned whether prejudice reduction should ultimately be our primary goal; instead, they suggest that greater emphasis needs to be placed on achieving broader social change toward intergroup equality (see, e.g., Cikara & Paluck, 2013; Dixon et al., 2012; Wright & Lubensky, 2009). Importantly, as noted by McConahay (1978), "amicable relations among racial and ethnic groups can exist alongside grossly unjust inequalities" (p. 77). Moreover, with its stated goal of prejudice reduction, this literature has tended to focus on shifting prejudiced attitudes among members of dominant and historically advantaged groups—an approach that is likely to focus research efforts on attitudes and social relations between members of different groups, rather than on the structural inequalities that shape the nature and contours of intergroup relations (Dixon et al., 2017). Moreover, given their relatively privileged position in the status hierarchy, members of dominant groups are less likely to see or experience the structural disadvantages that exist in society relative to members of minoritized groups, who are more directly affected by them (Eibach &

Ehrlinger, 2006; Knowles et al., 2014; Sidanius & Pratto, 1999). In turn, members of dominant groups may be inclined to see societal inequalities as being rooted mostly in social attitudes and relations, rather than in terms of institutional structures and systems that perpetuate intergroup disparities (Rucker et al., 2019; Salter et al. 2018).

Paralleling these views, Wright and Lubensky (2009) argue that “when efforts to reduce prejudice focus exclusively on getting dominant group members to think nicer thoughts and feel positive emotions about the disadvantaged group, they may not necessarily increase support for broader structural and institutional changes” (p. 18). At the same time as they acknowledge that “efforts to reduce rampant antipathy, overt expressions of hostility, and active denigration of other groups would need to be part of a scheme to improve many intergroup relations,” Wright and Baray (2012) also add that it “appears reasonable to consider the limitations of a focus on prejudice reduction, and recognize that it may actually directly conflict with another important means by which positive social change occurs” (p. 242). And as stated particularly forcefully by Dixon et al. (2012), “we need to ask ourselves if prejudice reduction deserves its status as the preeminent framework through which we approach the problem of ‘improving’ relations between groups within historically unequal societies” (p. 425). In the paragraphs that follow, we discuss in more depth how these concerns associated with the prejudice reduction approach relate to the specific strategies of intergroup contact and common group identities.

Intergroup contact. Given the central role that group status plays in shaping relations between groups (Bobo, 1999; Sidanius & Pratto, 1999), intergroup contact research over the last twenty-five years has identified a number of asymmetries in experiences of intergroup contact among members of dominant and minoritized groups. While both are likely to feel anxious and apprehensive about engaging in intergroup contact (Plant & Devine, 2003; Shelton et al., 2006), their anxieties are likely to be based in different concerns: members of dominant groups are likely to experience anxiety about being perceived as prejudiced, whereas members of minoritized groups are more likely to be anxious about being targeted by prejudice (Devine & Vasquez, 1998). Correspondingly, members of dominant groups typically seek reassurance of their moral integrity (e.g., that they are “liked” and seen as “good people”), while members of minoritized groups instead tend to seek respect and desire to feel empowered (Bergsieker et al., 2010; Shnabel et al., 2009). Members of dominant groups also prefer to avoid discussions of group differences during contact, whereas members of minoritized groups typically prefer to address structural inequalities directly and discuss differences in status and power relations between the groups (Kteily et al., 2013; Saguy & Dovidio, 2013).

Newer generations of contact research have also uncovered notable asymmetries in the effects of intergroup contact among members of dominant and minoritized groups. On average, the beneficial effects of contact on prejudice reduction tend to be weaker among members of minoritized groups, relative to the effects typically observed among members of dominant groups (Binder et al., 2009; Tropp & Pettigrew, 2005b)—a finding due in part to the pervasiveness of discrimination faced by minoritized groups in their relations with the dominant group (Tropp, 2007). At the same time, growing evidence suggests that while greater intergroup contact typically corresponds with greater awareness of inequality, greater support for social change, and greater participation in efforts to promote social change toward equality among members of dominant groups, greater intergroup contact tends to be associated with lower perceptions of discrimination, less support for social change, and lower levels of participation in efforts to promote social change toward equality

among members of minoritized groups (e.g., Cakal et al., 2011; Dixon et al., 2010a; 2010b; Hässler et al., 2020; Reimer et al., 2017; Selvanathan et al., 2018).

Common group identities. Some parallel asymmetries in preferences and perspectives of members of dominant and minoritized groups have been observed in relation to common group identities. Due to status differences in the larger society, members of dominant racial groups (e.g., White Americans) tend to be viewed as more representative and prototypical of the common group as a whole (e.g., “Americans”) as compared to minoritized racial groups in the same society (e.g., Asian Americans, Black Americans; see Devos & Banaji, 2005). The norms, values, and standards of the dominant group are also more likely to be projected onto the common group as a whole, relative to those of minoritized groups (see Mummendey & Wenzel, 1999; Wenzel et al., 2003). As a consequence, members of minoritized groups are more likely to feel their distinct subgroup identity is merely being subsumed within the larger superordinate category, while wanting to ensure their distinct subgroup identity is valued and acknowledged, in spaces where diverse groups are brought together as part of a larger whole (Crisp et al., 2006; Eggins et al., 2002; Hornsey & Hogg, 2000). Indeed, considerable work now suggests that dominant groups tend to prefer singular representations of common group identities, where all parties are merely regarded as part of a single, shared superordinate category (i.e., one group representations); by contrast, members of minoritized groups prefer representations that highlight both their distinct subgroup identities and their inclusion in the superordinate category (i.e., dual group representations; Dovidio et al., 2000, 2008).

Relatedly, these preferences for group representations within common group identities correspond with group members’ ideological orientations and conceptions of diversity (see Berry, 2001; Dovidio et al., 2009; Rattan & Ambady, 2013). Paralleling their preferences for one group representations, members of dominant groups typically favor colorblind ideologies that align with assimilationist perspectives, in that they downplay group differences and focus on commonalities across all within the larger whole. Instead, and in line with their preferences for dual group representations, members of minoritized groups tend to favor multicultural ideologies that align with perspectives highlighting diversity, by emphasizing and valuing group differences that exist within the larger whole (Dovidio et al., 2016; Plaut et al., 2009; Rattan & Ambady, 2013; Ryan et al. 2010). Importantly, these asymmetries in ideological orientations also carry broader societal implications: one group representations of common group identities may help to maintain the group status hierarchy by deflecting attention from group-based disparities and masking inequalities that exist between the groups included therein (Dovidio et al., 2016; Neville et al., 2013); moreover, presenting one group representations of common group identities may in turn lead people to perceive less inequality between groups, and therefore less of a need for social change to promote equality (Dovidio et al., 2016; Ufkes et al., 2016).

5. ADDRESSING STRUCTURAL INEQUALITIES IN PREJUDICE REDUCTION STRATEGIES

Many of the key shortcomings of prejudice reduction approaches summarized above may be aided through addressing structural inequalities directly when groups are brought together

to interact or as part of a common group identity. Emerging research on intergroup contact and common group identities has purposely pursued these precise issues, to identify pathways and mechanisms through which these prejudice reduction approaches can serve both to improve attitudes and relations between groups and to promote ever-greater levels of societal equality.

A growing body of evidence demonstrates that intergroup contact need not undermine minoritized group members' support for social change toward equality when the contact includes explicit acknowledgment of group differences in status or power—such as communicating respect for the minoritized group (Glasford & Johnston, 2018) and empowering the minoritized group (Hässler et al., 2021), as well as having minoritized group members receive confirmation from dominant group members that status inequalities are illegitimate (Becker et al., 2013), and/or that they support efforts to promote intergroup equality (Droogendyk et al., 2016; see also Louis et al., 2019). Among both dominant and minoritized groups, greater intergroup contact is also associated with greater willingness to work in solidarity across group lines to promote social change toward equality (Hässler et al., 2020). These tendencies are likely to be strengthened further the more members of these groups communicate about group differences in status and power during their contact (Tropp et al., 2021; Hassler et al., 2021). Conversations about structural inequalities with minoritized groups can also afford dominant groups with greater insights into and awareness of their own relative privilege (Nagda & Gurin, 2007; Nordstrom, 2015), which in turn can foster their greater motivation to take action for social equality (Tropp et al., 2021). Along with the efforts of minoritized groups, support and motivation for social equality among dominant groups has often been regarded as integral for creating successful social movements and sustainable social change to promote equality, because of their greater access to societal resources and their lesser potential to encounter resistance from others in the dominant group as they work to achieve more equitable societal outcomes (Dovidio et al., 2016; Glasford & Johnston, 2018; Hässler et al., 2021; Subašić et al., 2008; see also Craig and Phillips, Chapter 23, this volume).

Parallel trends have also been observed with respect to how common group identities are framed and represented. Recent studies show that dual identity representations—where group members identify strongly with both the common group (e.g., national group) and their distinct subgroup (e.g., ethnic group)—encourage members of minoritized groups to sustain commitment to social change to promote equality (Glasford & Dovidio, 2011; Ufkes et al., 2016; van Stekelenburg and Gaidyte, Chapter 26, this volume), even after experiencing positive contact with the dominant group (Pereira et al., 2017). At the same time, we recognize that members of dominant groups tend to prefer one group representations to dual group representations of common identities (Dovidio et al., 2000), likely because “recognizing both difference and commonality may be less comfortable than emphasizing only common identity, colorblindness, and assimilation” (Dovidio et al., 2016, p. 133). Yet recognizing both differences and commonalities through dual group representations could potentially yield benefits for dominant and minoritized groups alike (see Banfield & Dovidio, 2013), and particularly when dominant group members feel that their own subgroup identities are recognized and valued as part of a larger multicultural entity (see Plaut et al., 2011).

6. ADDRESSING METHODOLOGICAL ISSUES IN PREJUDICE REDUCTION RESEARCH

Beyond conceptual critiques of prejudice reduction strategies, there have also been a number of methodological critiques leveled at the research literature on prejudice reduction. Particularly in reference to research on intergroup contact, some critiques have focused on the preponderance of cross-sectional survey studies that only examine patterns of associations among relevant variables and provide little interpretive insight regarding possible causal effects in prejudice reduction (see Christ & Wagner, 2013; O'Donnell et al., 2021). Newer generations of contact research have responded directly to these concerns by conducting long-term, and often multi-year, longitudinal studies that allow for assessments of how changes in contact correspond with changes in intergroup attitudes over time (e.g., Binder et al., 2009; Levin et al., 2003; see also Christ et al., 2012). Focused mostly on racial and ethnic relations, such studies suggest that both causal paths are in operation: greater contact with other racial and ethnic groups typically reduces prejudice over time, and people who are initially more prejudiced tend to avoid contact with other racial and ethnic groups.

Longitudinal studies in this area have continued to grow more methodologically rigorous and sophisticated in recent years. By incorporating latent change models and social network models into longitudinal designs, researchers can examine within-individual variability in contact and prejudice scores and the degree to which changes in individuals' levels of intergroup contact are associated with changes in their levels of prejudice over time (see, e.g., Bracegirdle et al., 2022; Christ & Wagner, 2013; O'Donnell et al., 2021; Wölfer et al., 2016). This work has revealed considerable within-individual variability in the degree to which associations between contact and prejudice change over time (Dhont et al., 2012), as well as showing that greater contact may also shift individuals' propensities to be prejudiced over time, as indicated by change in their social dominance scores (Dhont et al., 2014).

Combining elements of longitudinal and cross-sectional research designs, cross-sequential studies have also begun to clarify how associations between contact and prejudice may vary due to both processes of human development and the psychological processes through which attitudes are formed and transformed over time. As one notable example, Wölfer et al. (2016) recruited four cohorts of Swedish youth (aged 13, 16, 20, and 22 years at the start of the study, $N = 3815$) for a four-wave, multi-year longitudinal study of changes in intergroup contact and intergroup attitudes. In line with earlier research, these authors observed that greater contact was associated with more positive intergroup attitudes across all cohorts. Latent growth curve models also showed that contact yielded particularly strong effects in shaping intergroup attitudes among the younger cohorts of adolescents, as compared to the effects of contact observed among the older cohorts of young adults whose intergroup attitudes had begun to crystallize. Thus, the authors conclude that early contact experiences may not only be important drivers of youth's developing intergroup attitudes, but these early experiences may also increase their willingness to engage in future intergroup contact as they enter into adulthood (see also Sears & Brown, Chapter 3, this volume).

Other methodological critiques specify that experimental research designs in field settings should be favored (e.g., Paluck et al., 2021), due to their ability “to assess causal relationships” and “whether an intervention’s effects emerge and endure among the cacophony of real-world influences including larger political and economic changes and proximal social pressures and distractions” (Paluck & Green, 2009, p. 357). We agree that more experimental studies conducted in field settings—with diverse populations of participants from different societal contexts around the world (see, e.g., Littman et al., 2021; Mousa, 2020)—have unique strengths that can contribute meaningfully to the prejudice reduction research literature. Still, we believe that valuable information may be gained through a variety of research methods, and their synthesis (see Brewer & Hunter, 2006), such that many approaches should be harnessed to study a phenomenon as complex and multifaceted as prejudice reduction. As stated by Paluck et al. (2021), it would be fruitful “to pull from all corners of behavioral science to develop feasible, transportable, and sustainable ways to end prejudice” (p. 555).

We also wish to highlight that outcomes may vary not only in relation to the prejudice reduction strategies used (e.g., contact, common group identity), how they are implemented (e.g., dosage, time scale), and how studies are designed to evaluate them (e.g., experimental, longitudinal), but also in relation to the nature of the intergroup context and how relevant outcomes are assessed. On the whole, greater degrees of societal inequality, instability, and/or violence should naturally present greater challenges to detecting prejudice-reducing effects, as such features of the context typically provoke and sustain heightened levels of intergroup threat (Kende et al., 2018; Tropp, 2015; Wagner & Hewstone, 2012), which can reinforce long-standing narratives of conflict between groups (Bar Tal, 2007). At the same time, although prejudice reduction is often conceptualized as a single process, it may actually involve several related psychological processes, such that it may involve reducing initial feelings of intergroup threat or anxiety in order to allow space for the possibility of having positive intergroup attitudes eventually emerge (see, e.g., Page-Gould et al., 2008; Pettigrew & Tropp, 2011; Reimer et al., 2021; Swart et al., 2011). Thus, depending on levels of pre-existing intergroup hostility or conflict in a given context, it is possible that prejudice reduction efforts may yield less overt hostility between groups without full intergroup trust or inclusion (e.g., Dehron et al., 2021; Tropp & Mallett, 2011), or more positive feelings toward individual members of other groups without broader generalization of intergroup attitudes (e.g., Mousa, 2020). We therefore advise researchers and practitioners to attend closely not only to the prejudice reduction strategies and methodologies they intend to use, but also to consider what types of prejudice reduction outcomes are realistic in light of the social and political contexts in which prejudice reduction strategies are being implemented and evaluated (see also Pettigrew, 2021; Tropp, 2015; Wagner & Hewstone, 2012).

7. SOCIAL CHANGE

Rather than pursuing the goal of prejudice reduction, other scholars would instead encourage greater emphasis on promoting social change (e.g., Cikara & Paluck, 2013; Dixon et al., 2012); yet, somewhat disparate literatures on social change currently exist in social and political psychology. A considerable amount of research has considered factors that

motivate people to become involved in collective efforts to promote social change toward equality (see, e.g., Klandermans, 1997; Tajfel & Turner, 1986; Van Zomeren et al., 2008). Originally, research in this area focused on the perspectives and motivations of historically disadvantaged and minoritized groups who sought to improve their position, or the position of their group, with the existing status hierarchy. This work has stressed the importance of identification with the disadvantaged group and recognition of the group's disadvantaged position as motivating forces for collective action in response to social inequality (Tajfel & Turner, 1979; Wright & Tropp, 2002; Pérez and Vicuña, Chapter 25, this volume). Other driving factors include group members' perceptions of the permeability, legitimacy, and stability of the status hierarchy (Shuman et al., 2016; Tajfel & Turner, 1986), as well as their moral convictions and beliefs about the likelihood of the group's success in effecting change (Van Zomeren et al., 2008; 2012). More recently, the scope of research in this area has also been extended to consider factors that might motivate dominant groups to support change toward greater equality. Although dominant groups are generally motivated to maintain and support the status quo from which they benefit (Bobo, 1999; Sidanius & Pratto, 1999), emerging research suggests that members of dominant groups can become activated to promote social equality due to their moral convictions (e.g., Van Zomeren et al., 2011), as well as through meaningful contact experiences with members of minoritized groups (e.g., Cakal et al., 2021; Craig and Phillips, Chapter 23, this volume; Hässler et al., 2020; Selvanathan et al., 2018; Tropp & Uluğ, 2019).

While these perspectives have shed great light on the motivating factors that propel people to support social change at the individual level, they do not yet specify strategies through which broad-scale social change might be achieved. Other branches of the social science research literature have instead examined factors that contribute to changes in public opinion and behaviors in civic life, including indicators of equality and inclusion as established through broad social policies (*institutional context*; see, e.g., Sullivan et al., 1985; Weldon, 2006), as well as perceived norms for intergroup relations in particular communities or social contexts (*social norms*; see, e.g., Blinder et al., 2013; Sechrist & Stangor, 2005).

8. SOCIAL CHANGE THROUGH INSTITUTIONAL CONTEXT

Scholarship on institutional context highlights ways in which societal and political institutions—and particularly those established through relevant laws and government policies—contribute to shaping public attitudes toward various groups (Weldon, 2006). Within a given institutional context, societal and political institutions, and the influential actors within them, define rules, policies, and standards for conduct that shape the nature of public discourse and narratives regarding how groups are to be treated (Weldon, 2006), as well as how people from different groups are expected to relate to each other (Pettigrew, 1991). These policies and standards may be framed in relatively exclusionary or inclusionary terms, such that they deny or provide certain opportunities or resources to designated constituents, and in turn serve as cues regarding whether certain groups should be excluded or included (Jiménez et al., 2021; see also Huddy, Chapter 21, this volume).

Recent studies from across Europe and North America indicate how the institutional context of a given society can shape public attitudes toward minoritized groups in that society (see de la Sablonnière et al., 2020; Huo et al., 2018; Ofosu et al., 2019; Schlueter et al., 2013). As one illustrative example, Schlueter et al. (2013) linked ratings of immigrant integration policies at the national level from the 2016 Migration Integration Policy Index (MIPEX, see Huddleston et al., 2017) to individual-level survey data gathered through the Eurobarometer (2009, 25 countries) and the European Value Study (2008–2009). In both cases, multi-level models revealed that more inclusionary immigrant integration policies corresponded with lower reported perceptions of threat posed by immigrants among members of the host societies. Similar associations were observed between MIPEX ratings of national immigrant integration policies and public attitudes toward Muslims assessed through the European Social Survey (2014–2015); more inclusionary integration policies were associated with less negative attitudes toward Muslims, an effect that persisted even when statistically controlling for the proportion of Muslim residents in the national context (Schlueter et al., 2020).

In another line of research examining how institutional context can shape individuals' attitudes, Ofosu and colleagues (2019) gathered responses to implicit and explicit measures of anti-gay prejudice from approximately 1 million individuals who completed these measures via Project Implicit over a 12-year period (<https://implicit.harvard.edu/>). By geolocating these individuals and tracking the dates of their responses, the authors were able to examine scores on measures of anti-gay prejudice before and after legislation passed legalizing same-sex marriage in each state. Overall, the authors observed that both implicit and explicit forms of anti-gay prejudice tended to decrease in recent years. However, their results also showed steeper decreases in anti-gay prejudice following legalization of same-sex marriage at the state level—a finding the authors replicated using a nationally representative sample from the United States (based on data from the American National Election Studies, www.electionstudies.org).

9. SOCIAL CHANGE THROUGH SOCIAL NORMS

Alongside policies established by the institutional context, considerable research suggests that people's expressed attitudes and behaviors toward other social groups may also be shaped through social norms (see Crandall et al., 2002; Pettigrew, 1991; Sherif, 1936). Norms involve socially shared perceptions of the ways in which people typically behave or should behave (see Miller et al., 2000; Paluck, 2009). Whereas a person may be subject to legal reprimands if they fail to follow established policies, the repercussions of a person's failure to follow social norms are more likely to be based in forms of social disapproval than formal censure (Young, 2008).

Social norms pertaining to intergroup relations can be communicated and absorbed through a variety of means. Intergroup norms relevant to public opinion may be inferred in response to established social policies (e.g., de la Sablonnière et al., 2020; Schlueter et al., 2013; Tankard & Paluck, 2017). Normative messages about intergroup relations can also be transmitted through media sources (e.g., Bilali et al., 2017; Hameiri et al., 2016; Paluck, 2009), and people may perceive norms of approval or disapproval regarding intergroup

relations in their immediate social environments, based upon the expressed attitudes and observed behaviors of others (e.g., Blanchard et al., 1994; Stangor et al., 2001, Tankard & Paluck, 2016).

Complementing the research on institutional context described above, an experimental study by Huo et al. (2018) suggests how perceived norms regarding state-level policies may shape individuals' attitudes toward particular groups. Ostensibly as part of a study on news reporting (Study 1), White US citizens were asked to read and rate several headlines, including one that was varied randomly across experimental conditions to suggest that residents of their state supported proposed legislation that would either encourage local immigration (welcoming condition) or discourage local immigration (unwelcoming condition). After reading the news headlines, participants indicated their attitudes toward a variety of social groups, including Whites, Americans, Latinos, and legal immigrants, among others. While no significant differences in attitudes toward Whites or Americans were observed across experimental conditions, White American participants who were exposed to a headline indicating that legislators and residents of their state would welcome local immigration reported more positive attitudes toward legal immigrants and Latinos, as compared to those exposed to a headline indicating that legislators and residents of their state would not welcome local immigration. Thus, the authors conclude that perceived support for immigration from state legislators and local residents can shape White Americans' inclinations to be more or less favorable toward groups associated with immigration in their home communities.

Research by Murrar et al. (2020) provides another notable research example. These authors developed professional-quality posters representing data they had gathered previously to convey the norm that most students at their university value diversity. In one study (Study 2), university classrooms were randomly assigned to have several of these posters present (social norms condition) or not present (control condition) during the first 5 weeks of the academic semester. Near the end of the semester (weeks 10–12), students enrolled in courses that took place in these classrooms were then asked to complete measures concerning their own attitudes toward diversity. Results showed that students in classrooms with posters representing pro-diversity social norms early on in the semester reported significantly more supportive attitudes toward diversity toward the end of the semester, as compared to students in classrooms where no such posters were present. Thus, the presence of normative messages demonstrating support for diversity among others within the institution contributed to shaping students' own attitudes toward diversity.

By learning and subscribing to norms that are operating in one's local environment, people can gain a greater sense of belonging and avoid social rejection or disapproval (Tankard & Paluck, 2016). People are also especially likely to attend to normative information from influential others (Hogg & Van Knippenberg, 2003; Paluck & Shepherd, 2012). In intergroup contexts, people will attend closely to the norms enacted or espoused by members of their own groups, whose expressed attitudes and behaviors serve as influential guides for their own attitudes toward and social relations with members of other groups (e.g., Abrams et al., 1990; Crandall & Eshleman, 2003; Terry & Hogg, 1996). Thus, people's willingness to express intergroup prejudice closely tracks the social norms they perceive from fellow group members, and the extent to which they deem prejudice against certain groups to be socially acceptable (Crandall et al., 2002; Durrheim et al., 2016). Additional research in diverse intergroup contexts also shows that people may attend to cues from both

members of their own group and other groups, as both can serve as useful sources of information for guiding intergroup relations (e.g., Gómez et al., 2011; Wout et al., 2014; Tropp & Bianchi, 2006).

10. SOCIAL CHANGE STRATEGIES: CHALLENGES AND SHORTCOMINGS

While institutional and normative approaches to promoting social change can be quite influential, there are also some challenges and limitations associated with their use. One set of challenges pertains to the fact that social norms are constantly in the process of changing (Crandall et al., 2002). Particularly when nations and communities are in the midst of major transformations, such as those involving rapid demographic shifts (Craig et al., 2018), emergent social movements (Crutchfield, 2018), or political polarization (Kingzette et al., 2021), there may not be widespread consensus regarding what prevailing norms are or should be, and attempts to establish one clear, standard set of norms is likely to be contested (Pettigrew, 1991). In the words of Sherif (1936), “such a delicate, unstable situation is the fertile soil for the rise of doubts concerning the existing norms, and a challenge to their authority” (p. 86).

In the absence of normative consensus, urging people to comply with norms to which they do not subscribe can also incite backlash (Legault et al., 2011), and may even provoke feelings of anger and resentment (Pettigrew, 1991; Plant & Devine, 2001). As one illustrative example, Legault et al. (2011) presented non-Black participants with one of three versions of a brochure that were randomly assigned across experimental conditions; one version encouraged compliance with non-prejudiced norms (norm compliance condition), one version described the importance and value of being non-prejudiced (prejudice reduction condition), and one version simply provided participants with a definition of prejudice (control condition). After reading through the brochure, each participant then completed measures tapping their reported prejudice toward Black people and their motivation to be non-prejudiced. Results showed that participants in the norm compliance condition reported significantly greater prejudice toward Black people than participants in either the control condition or the prejudice reduction condition, along with showing motivations to be non-prejudiced comparable to participants in the control condition. Together with other work (e.g., Devine et al., 2002), these findings suggest that norms encouraging people to be non-prejudiced can unintentionally reinforce some people’s willingness to express prejudice, to maintain a sense of autonomy or personal control (see also Legault et al., 2007).

Furthermore, if and when any consensus emerges regarding norms and standards for conduct concerning relations between groups, there may still not be broad agreement or shared understandings about whether and how those norms and standards are being followed or enacted. Members of dominant and minoritized groups often have quite divergent views regarding what “equality” looks like, or what it might ultimately take to be achieved (Lewis, 2021). Relatedly, groups in conflict tend to differ in their views about what realizing peace should entail, and their perceptions can vary depending on their relative positions of power: groups high in power are typically more inclined to conceptualize peace in terms of intergroup harmony, whereas groups low in power are more inclined

to conceptualize peace in terms of achieving justice or receiving fair treatment (Leshem & Halperin, 2020; Saguy et al., 2013). Corresponding to their power and status positions, groups may also vary in how they see and evaluate progress toward social change, such that dominant groups with greater power typically perceive greater progress toward social equality than groups with less power who have been minoritized in society (Kteily & McClanahan, 2020; Richeson, 2020).

11. PREJUDICE REDUCTION AND SOCIAL CHANGE: POINTS OF CONNECTION AND INTEGRATION

Given that strengths and challenges are associated with common strategies used to foster both prejudice reduction and social change, we seek to highlight ways in which merits of these approaches can complement and bolster each other. Like other scholars (e.g., Jones & Dovidio, 2018; Hässler et al., 2021), rather than framing prejudice reduction and social change as incompatible goals, we subscribe to a “both-and” approach that incorporates contributions afforded by these (and other) frameworks, toward the dual goals of improving attitudes and relations between groups and achieving ever-greater levels of social equality and justice. Working toward these joint goals will necessarily involve multiple dimensions of social life and multiple levels of analysis, ranging from the attitudes and motivations held by individuals, to their interactions with others as members of social groups, to social norms and structures that shape the spaces in which diverse groups live and engage with each other (see Jones & Dovidio, 2018; Pettigrew, 2021). In turn, the strategies and interventions we devise to address these challenges will necessarily require efforts at both individual and societal levels (Lewis, 2021; Richeson 2018), such that we must begin to envision how approaches typically used to promote prejudice reduction and social change relate to and can inform each other.

At the interface of these approaches, some scholars suggest that a great deal of work has focused on how social norms shape individuals’ attitudes and behaviors, yet more attention should be granted to understanding how individual-level attitudes help to create and sustain norms that can foster social change (Durrheim et al., 2016). Others propose that these processes may occur on varying time scales, such that implementing changes in the normative climate can serve as an effective and efficient way to shift individuals’ attitudes and behaviors in the short term, and that such changes at the individual level carry the potential of changing ways in which people will be socialized in the longer term (Crandall et al., 2002). More broadly, these efforts suggest that the fields of social psychology and political psychology are ripe for greater empirical and theoretical integration of scholarship on prejudice reduction and social change.

A number of researchers have embarked on such integrative investigations in recent years, linking normative processes and policies to individuals’ contact experiences and intergroup attitudes (see, e.g., Christ et al., 2014; Green et al., 2020; Kende et al., 2018; Pettigrew, 2021; Rosenfield, 2017). Some of this work has specified a “contextual effect” of intergroup contact.

Through multilevel analyses across seven large-scale surveys (five cross-sectional and two longitudinal), Christ and colleagues (2014) have shown that greater positive intergroup contact not only predicts lower levels of prejudice at the individual level, but also uniquely contributes to predicting more tolerant norms at the context level. As described by the authors, “prejudice is a function not only of whom you interact with, but also of where you live” in that “contact also affects prejudice on a macro-level, whereby people are influenced by the behavior of others in their social context” (Christ et al., 2014, p. 3999).

Other studies point to ways in which societal norms and institutional contexts might moderate prejudice reduction effects (Green & Staerkle, Chapter 28, this volume). For instance, Kende et al. (2018) linked country-level scores on measures of egalitarianism and support for hierarchy (Schwartz, 1992) to effect sizes reported in a large-scale meta-analysis of associations between intergroup contact and prejudice (Pettigrew & Tropp, 2006). With data from 660 samples in 36 cultural contexts, the authors observed that studies in contexts that scored higher in egalitarianism typically revealed stronger contact-prejudice associations, whereas studies in contexts that scored higher on support for hierarchy tended to show weaker contact-prejudice associations. Relatedly, Green et al. (2020) examined how the inclusiveness of country-level migrant integration policies (as determined by the Migrant Integration Policy Index, <https://www.mipex.eu/>) shape associations between everyday contact experiences and perceptions of intergroup threat as observed in the European Social Survey (Round 7). Based on responses from 32,093 citizens in 20 European countries, Green et al. (2020) found that everyday contact with people from other racial and ethnic backgrounds was generally associated with lower perceptions of intergroup threat; moreover, the links between everyday contact and reduced threat were stronger in countries with more tolerant migration policies (high MIPEX scores) as compared to the contact-threat links observed in countries with less tolerant migration policies (low MIPEX scores).

Some quasi-experimental studies have also examined boundary conditions for contact effects, by testing whether and how contact-based interventions might reduce prejudice in contexts where prejudice toward minoritized groups is normative, blatant, and commonplace—such as anti-Roma prejudice in Hungary (see Kende et al., 2017a; Orosz et al., 2018). In collaboration with the Living Library program sponsored by European Youth Center Budapest (Council of Europe), Orosz et al. (2016) studied Hungarian participants’ responses to facilitated conversations with members of minoritized groups who were willing to share their experiences with prejudice, discrimination, and social exclusion. In some cases, program participants engaged with a member of the Roma community, and in other cases, program participants engaged with members of other minoritized groups (e.g., LGBT). Surveys administered before and after participation in the program assessed Hungarian participants’ own attitudes toward Roma people, and how much they believed their friends would be willing to accept and engage in contact with Roma people, as an indicator of perceived peer norms. Results showed that pre-program attitudes toward Roma people were comparable among Hungarians who did or did not engage with a member of the Roma community; however, Hungarians who engaged with a Roma person reported significantly less prejudice toward Roma people after participating in the program, as compared to Hungarians who did not engage with a Roma person during the program. Moreover, these patterns of effects were consistent irrespective of whether participants perceived their friends to be more or less accepting of Roma people.

In another quasi-experiment, and given the extreme underrepresentation of Roma students at their university, Kende et al. (2017b) gave Hungarian students an opportunity to meet with a Roma student at their university outside of regular academic hours. Recruited from randomly selected sections of undergraduate psychology courses, 64% of the Hungarian students enrolled agreed to participate, and their initial attitudes toward Roma people did not significantly differ from those who chose not to participate (means scores of 2.49 and 2.54 on a 5-point scale). Students who elected to participate were then paired with a Roma student for a 60-minute conversation, during which they took turns asking and responding to questions designed to foster closeness and mutual self-disclosure (see Aron et al., 1997). Both participating and non-participating students were once again asked to report their own attitudes toward Roma people, as well as their perceptions of institutional support for minimizing anti-Roma prejudice (at the classroom, university, and state levels). Results indicated that students who engaged in conversation with a Roma partner reported significantly more positive attitudes toward Roma people in general after this experience, while there was no significant difference in attitudes toward Roma people among students who did not engage in conversation with a Roma partner. Perceived institutional support also moderated effects of this contact intervention, such that the prejudice-reducing effect was especially pronounced among participants who perceived stronger institutional norms countering anti-Roma prejudice.

These contact-based interventions were short in duration, and little is known regarding whether their effects would persist over time. However, multi-level analyses of panel data from nearly 900 Hungarian adolescents provides further insight regarding these trends (Váradi et al., 2021). Váradi and colleagues observe that greater contact with Roma people is generally associated with less anti-Roma prejudice. At the same time, Hungarian adolescents also perceive that anti-Roma prejudice is normative among their classmates and teachers, and over time, many students adjust their attitudes to what they perceive to be the classroom norm.

Taken together, findings from this emerging body of work highlight many points of connection between processes associated with prejudice reduction and social change. As suggested by Durrheim et al. (2016), the “space” between individuals’ prejudices and social norms “is a site of genuine interaction . . . between people who define and contest the nature of prejudice” and “where expressions and definitions of prejudice can help to make or break norms” (p. 21). Viewed in this light, it becomes more natural to envision ways in which insights from the literatures on prejudice reduction and social norms can function in tandem to maximize our potential for fostering social inclusion and realizing social change toward greater equality.

12. PREJUDICE REDUCTION AND SOCIAL CHANGE: BRIDGING DIFFERENCES IN PERSPECTIVE

Nonetheless, and despite the great potential for further conceptual and empirical integration in research on prejudice reduction and social change, there have been some differences

in perspective and emphasis in these literatures that should not be overlooked. One point of divergence involves what is determined to be the goal of any given strategy or intervention to be implemented. Scholars focused on social norms tend to emphasize changing people's perceptions of others' attitudes and behaviors, so that they may be motivated to engage in behaviors that correspond with those perceived norms (e.g., Cialdini & Trost, 1998; Paluck et al., 2021; Tankard & Paluck, 2016). Scholars in the prejudice reduction tradition have instead tended to focus on how people experience and respond to relations with different others, so that they may be motivated to change how they think about, feel, and behave toward members of other groups (e.g., Allport, 1954; Brown & Hewstone, 2005; Pettigrew, 1998; Tropp & Pettigrew, 2005a). In this sense, from the perspective of many prejudice reduction researchers, the goal is not simply to change people's evaluations of another group, but rather to reconfigure their construals and understandings of relations between groups *in relationship with each other* (Frey & Tropp, 2006; Gaertner & Dovidio, 2000). As such, rather than thinking about prejudice reduction merely as an instance of attitude change toward any given attitude object (e.g., recycling; see Tankard & Paluck, 2016), prejudice reduction strategies are inherently relational in nature, such that they may not only spark change in how people relate to and feel toward other groups, but they may also transform how people see themselves and their own groups in relation to other groups (see Brewer, 2008; Gaertner & Dovidio, 2000; Pettigrew, 1997; Tropp & Barlow, 2018).

This difference in perspective points to another potential point of divergence between the literatures on prejudice reduction and social change as they currently exist—namely, how they regard adherence to, versus internalization of, prevailing social norms (see Crandall et al., 2002; Kelman, 1958). Among many researchers who study norms, observing adherence to without private acceptance or internalization of prevailing social norms is not inherently problematic, provided that this adherence to norms produces the desired behavior. However, this presumed lack of internalization may not sit well with many researchers who study prejudice and prejudice reduction, who often desire to foster “an internalized, personal commitment to egalitarianism” (Kunstman et al., 2013, p. 443; see also Plant & Devine, 1998), and who acknowledge that people's motivations may be questioned, or their behaviors may be regarded merely as performative, without some evidence of sustained commitment or internalization (see, e.g., Morris, 2020).

What, then, might help to make further integration of perspectives on prejudice reduction and social change as useful and generative as possible? At the very least, we must articulate the goals and intended outcomes of our research and interventions clearly (are we seeking only to reduce prejudice? only to produce behavior change? or might other outcomes also be relevant?), while specifying the level(s) of analysis at which we seek to effect change. Rather than conflating discussions of strategies and levels—such as presuming that prejudice reduction studies are only relevant to individual-level processes, and social change studies are only relevant to societal-level processes—we should remain open to and explore the possibility that these approaches may involve multiple social and psychological processes and have impacts at multiple levels (see also Jones & Dovidio, 2018; Pettigrew, 2021).

Here, it might be particularly useful for researchers to consider the time scales within which intended effects are expected to occur. As stated by Jones and Dovidio (2018), “in order for both-and solutions to be found, the time frame may need to be expanded . . . taking a long view may open up possibilities that a short view is unable to envision” (p. 33).

Researchers in the prejudice reduction and social change traditions have both suggested ways in which the processes they study may be shaped or influenced by the passage of time. For instance, what initially emerges through compliance to social norms may eventually become internalized due to repeated feedback and continued socialization from fellow group members in response to one's expressed attitudes and behaviors (Crandall et al., 2002; Sherif, 1936). Interactions between strangers from different groups may initially be threatening and stress-provoking (MacInnis & Page-Gould, 2015), but these tendencies can attenuate over time as people gain greater experience, familiarity, and comfort engaging with others across group lines (Page-Gould et al., 2008; Tropp, 2021). Highlighting group differences can also enhance perceptions of threat and competition between groups—thus, reducing the salience of group differences during the early stages of contact may help to curb the escalation of intergroup competition and conflict, with an understanding that group differences must be addressed at later points of the intergroup relationship to address structural inequalities that exist between groups (see, e.g., Dovidio et al., 2016; Hässler et al., 2021; Pettigrew, 1998). Considering issues of timing and sequence may help us to gain purchase on the nature and roles of social and psychological processes in our ongoing efforts to dismantle prejudice and promote social change.

Along with considering temporal dimensions of the processes we study, we must also attend closely to the social and political contexts in which we study prospects for prejudice reduction and social change. Rather than being inclined to make wholesale claims about the effectiveness (or lack of effectiveness) of varied strategies, such an approach may help to ensure that we learn how these social and psychological processes may manifest and function similarly or differently across contexts (see Pettigrew, 2021). For example, people may be more or less willing to engage in intergroup contact, or to exhibit long-lasting attitude change as a result of intergroup contact, depending on the intensity and/or severity of conflict, violence, segregation, and inequality between groups in their communities (e.g., Kende et al., 2018; Knowles & Tropp, 2018; Mousa, 2020; Wagner & Hewstone, 2012). Alternatively, people may be more or less inclined to endorse or promote social change depending on normative expectations, opportunity structures, and repressive systems in their local environments (e.g., Corcoran et al., 2011; Uluğ et al., 2021). As stated eloquently by Dixon et al. (2017), framing prejudice reduction and social change merely as in opposition to each other could be “potentially as limiting as the presumption that the two models of change are simply compatible . . . the deeper challenge will be to explore how the relationship between these two models of change plays out within particular social contexts and to specify the conditions under which interventions based on these models are effective, ineffective, or even counterproductive in creating a more just society” (p. 495).

13. CONCLUSION

In this chapter, we have endeavored to review the vast, and often disparate, research literatures on prejudice reduction and social change, while highlighting how scholarship in these areas might bolster each other and become more interconnected in future work. Rather than framing prejudice reduction and social change as goals that are inherently incompatible or in opposition to each other, we firmly believe that it could prove useful—both

for new empirical and theoretical developments, and for the interventions informed by our work—to envision ways in which the goals of prejudice reduction and social change may be pursued in tandem. We hope the reflections provided here encourage new collaborations and generative research directions that support joint efforts toward realizing greater social equality while improving attitudes and relations between social groups.

EMOTIONAL PROCESSES IN INTRACTABLE CONFLICTS

SMADAR COHEN-CHEN AND ERAN HALPERIN

1. INTRODUCTION

INTRACTABLE intergroup conflicts are extreme, prolonged, and violent forms of intergroup conflict, which involve unique socio-psychological dynamics (Bar-Tal & Halperin, 2013). As such, they offer challenges in using widely established and successful approaches to intergroup relations and harmony. One approach which has gained growing attention in this context addresses the role of emotions as an avenue to changing attitudes, behaviors, and even support for policies in intergroup intractable conflicts (Brader & Gadarian, Chapter 6, this volume). The role of emotional processes in conflicts can be studied from two very different perspectives. The first is a more descriptive one, in which scholars examine the role played by individuals' and groups' emotional experience in conflict situations. The second perspective, which has gained increasing attention in the recent decades, is a more interventionist one, focusing on the way emotional change (or regulation) can promote conciliatory attitudes and behaviors among the conflict's involved parties. The following chapter offers for the first time an integrative model, bringing together both the descriptive and the interventionist approaches. Put differently, this model encapsulates both the role of emotional experiences in preserving and perpetuating conflicts, and the potential role of emotion regulation in contributing to conflict resolution.

We begin by defining and discussing intractable conflicts, and their unique characteristics and dynamics. We then introduce the role of emotions in conflict, portraying first the descriptive approach, which elucidates how conflicts elicit emotions, and how emotions shape behaviors and policies in conflict in two ways. First, how emotions shape different stages of the conflict cycle, and second, the way emotions are experienced versus the types of intergroup outcomes they induce. Next, we add the interventionist approach, providing an overview of approaches to conflict resolution, and their limitations in addressing intractable conflicts specifically. We then incorporate the emotion-based interventionist approach into our model and demonstrate how two different approaches to emotion regulation (direct and indirect) come into play during the emotion generative process. Finally,

we discuss the main challenges and opportunities in studying emotional processes in intractable conflicts and offer some avenues for developing the field further.

2. INTRACTABLE INTERGROUP CONFLICTS

Intractable conflicts (Bar-Tal, 2007) are characterized by extreme, prolonged violence and involve unique socio-psychological dynamics that influence their nature and longevity. Coleman (2011) estimated that about 5% of conflicts in the world become intractable. The conflicts in the Middle East, Kashmir, Sri Lanka, Chechnya, Northern Ireland, and Cyprus constitute prototypical examples of intractable conflicts. While intractable conflicts evolve around very tangible and real issues (such as territory, security, and natural resources), which must be addressed in the resolution process, they are not merely severe forms of intergroup conflict. These conflicts are situations so extreme that although those involved understand that peace is in their best interest, they seem unwilling, and perhaps unable, to take the necessary steps toward conflict resolution (Bar-Tal, 2011; Fitzduff & Stout, 2006; Tropp, 2012).

2.1. Defining and Conceptualizing Intractable Conflict

In what ways are intractable conflicts unique? First, intractable conflicts are *protracted* and last at least one generation, creating a situation in which large parts of society have been born into a state of conflict, and are not acquainted with peaceful life conditions (Kriesberg, 1998). In addition to affecting the collective memory of the conflict, being unfamiliar with peace may make it hard for people in conflict to desire, and therefore act in order to promote, conflict resolution. Second, intractable conflicts cause widespread destruction and devastation. Although many intergroup conflicts may involve various forms of violent actions between the groups, intractable conflicts involve an ongoing cycle of wide-scale and extreme *violence* (such as war, occupation, terrorism, and limited military engagement), which escalates and de-escalates over time (Kriesberg, 1993, 1998; see also Snider et al., Chapter 14, this volume). This leads to another unique characteristic of intractable conflicts. The scope and sheer intensity of intractable conflict leads to *extensive investment* made by the parties involved. These investments are both physical (financial and military) and psychological (Kriesberg, 1993, 1998), which enable the group to withhold the difficult conflict situation (Bar-Tal, 2007).

Two further phenomena characterizing intractable conflicts involve the conflict's *centrality* and *totality* in the eyes of society members. While all intergroup conflicts exist in people's awareness and may be present in the collective narrative, intractable conflicts are highly predominant and play a central role in individuals' lives and decisions, as well as those of society as a whole. The conflict becomes so prevalent that it penetrates into almost all spheres in societal, cultural, educational, and political life and institutions, all of which become involved in the conflict and highly politicized. In essence, it is impossible for those involved in the conflict to ignore the situation or to stay neutral, since the conflict is forced upon them throughout their lives and in multiple domains (Bar-Tal, 1998, 2007).

Lastly, and perhaps most pertinent to this chapter, in addition to material factors, societies involved in intractable conflicts are characterized by a number of unique perceptions and attitudes. Parties in intractable conflicts hold an inherently *zero-sum perception* of the conflict. The fact that the conflict is highly multifaceted and complex, together with the continuous threats to security, lead to a perception of the issues in question not only as important but as existential to the group's very survival. And because both groups understand that winning is not a possibility, but equally will not compromise, intractable conflicts involve a perception that the *conflict is irresolvable*. Since both sides cannot win and are locked in a stalemate, both sides expect the conflict to continue forever, and they adjust accordingly both materially and psychologically to withstand the conflict far into the future (Kriesberg, 1993; Bar-Tal, 2007).

2.2. The Psychological Infrastructure of Intractable Conflicts

Contemporary literature on intractable conflicts describes a self-perpetuating cycle that when complete leads to conflict intractability (Bar-Tal & Halperin, 2011). As a result of the exposure to the extreme conditions of a long-lasting violent conflict, societies in such conflicts develop specific needs in their struggle for survival. Two of the most basic needs in this regard are maintaining a sense of normality in light of the abnormal situation that conflicts bring about, and the need to mobilize society for the collective conflict effort. Once these needs arise, psychological mechanisms develop in order to address them. For example, perceptions of ingroup righteousness or outgroup delegitimization can provide a sense of purpose and reason in the face of the doubt and helplessness that intractable conflicts often evoke. In other words, such psychological mechanisms are what people use in the attempt to try to live a normal life in abnormal conflict circumstances. Similarly, psychological mechanisms enable mobilization of group members without doubt or delay, which is crucial in an intractable conflict scenario.

These mechanisms are sustained and passed along between group members and taught across generations until they become a collective norm or standard. Over time, they establish into a complex sociopsychological infrastructure that both encompasses these elements and provides continuous psychological support and social mobilization. This infrastructure has been termed the culture of conflict or the psychological infrastructure of the conflict, and it consists of three main aspects: the *collective memory*, *ethos of conflict*, and *collective emotions* (Bar-Tal, 2007; Bar-Tal & Halperin, 2013; Bar-Tal et al., 2012). The developed infrastructure underlies the evolved culture of conflict and lays the groundwork for the reconstruction of a collective identity with characteristics reflecting the conflict context.

Collective memory is defined, according to Kansteiner (2002), as representations of the group's past, remembered by society members as their history and providing the epistemic foundation for the group's existence and continuity. Collective memory constructs the narratives, the symbols, and the myths related to the past that mold the culture of the group. Beliefs underlying collective memory, as a narrative, in the case of intractable conflict, evolve over time and become the history of the conflict to society members. Because collective memory is constructed to provide the epistemic basis and justification for the current goals and beliefs regarding the conflict, it provides an over-simplified, one-sided

historic narrative, which is inherently biased and distortive (Bar-Tal et al., 2012; Baumeister & Hastings, 1997). It revolves around four major themes: (1) The justification of the conflict, and its eruption and ensuing developments; relatedly, (2) the presentation of the ingroup as positive and (3) delegitimization of the outgroup; and lastly, (4) the victimization of the ingroup by the rival group. Past events that are unrelated to the conflict are often adapted and reinvented to serve the needs and goals associated with the conflict (Hammack, 2011; Hopkins, Chapter 9, this volume; Volkan, 1997). Importantly, the collective memory becomes, during times of escalation in which external parties become involved, an additional battleground over which the sides of the conflict fight to justify their actions (Bar-Tal & Halperin, 2013).

Ethos of conflict is defined as “the configuration of central societal beliefs that provide dominant characterization to the society and [give] it a particular orientation” (Bar-Tal, 2000, p. xiv). It is a relatively stable worldview, described as a conflict-specific ideology (Bar-Tal et al., 2012; Cohrs, 2012; Jost et al., 2009), which creates a conceptual framework that allows human beings to organize and comprehend the prolonged context of conflict in which they live and act toward its preservation or alteration in accordance with this standpoint. It provides the shared basis for societal membership, binds the members of society together, gives meaning to societal life, and imparts legitimacy to social order. The ethos of conflict is comprised of eight interrelated themes of societal beliefs (Bar-Tal, 2000; Bar-Tal & Halperin, 2013; Rouhana & Bar-Tal, 1998).

Societal beliefs about the justness of the ingroup's goals outline, justify, and rationalize the ingroup's goals, presenting them as existential and delegitimizing the justness of the outgroup's goals. *Societal beliefs about security* delineate the threats and dangers posed by the outgroup and conflict, functioning as a strong societal mobilizer to address said dangers when required. *Societal beliefs of positive collective self-image* refer to the ethnocentric tendency to attribute positive characteristics (e.g., courage, morality), to the ingroup as a way to differentiate the ingroup from the outgroup and establishing a sense of superiority and moral endurance (Sande et al., 1989). *Societal beliefs of the ingroup's victimization* refer to the presentation of the ingroup as the ultimate (and often only) victim, both generally but with a specific focus on the harm perpetrated by the outgroup (Bar-Tal et al., 2009; Schori-Eyal et al., 2014). These provide moral incentive to seek justice and oppose the outgroup, as well as to seek support from the international community. *Societal beliefs delegitimizing the opponent* place the outgroup and its members outside the boundaries of commonly accepted norms and groups, therefore justifying aggressive and inhumane treatment of the rival (Bar-Tal & Hammack, 2012; Haslam, 2006). *Societal beliefs of patriotism* create attachment and loyalty to the country and society, subsequently propagating sacrifice (including of members' own life) and encouraging willingness to endure hardships for the group (Huddy & Khatib, 2007; Huddy, Chapter 21, this volume). *Societal beliefs of unity* emphasize the importance of unity and social cohesion in the face of threat. These beliefs forge a sense of belonging and solidarity (Moscovici & Doise, 1994). Lastly, *societal beliefs of peace* shape peace as the group's ultimate wish and present the ingroup and peace-loving and pacifist. These beliefs bolster positive self-perceptions and external presentation of the group (Bar-Tal & Halperin, 2013). Together, these themes enable an understanding of society's present and past concerns as well as its future aspirations in the context of the conflict.

2.3. Intergroup Emotions

The unique psychological infrastructure involved in intractable conflicts, coupled with the one-sided perceptions and beliefs, turn intractable conflicts into fertile ground for the evolvment and perpetuation of intense group-based and collective emotions (Halperin, 2015). Emotions occur when an individual or a group appraises a situation as offering either important challenges or opportunities deemed to be relevant (Frijda, 1986; Scherer, 1984). This relevance can be based on individual goals and priorities, but also pertains to important social identities as well as symbolic and group-based goals (Tajfel & Turner, 1979). Therefore conflicts, which arise when two or more parties perceive their goals as directly contradictory and decide to act upon this basis (Kriesberg, 1993), are a quintessential breeding ground for a range of emotions. Collective or group-based emotions form the third and final layer of intractable conflicts' psychological infrastructure, because the emotions themselves are derived and created based on the ethos of the conflict and collective memory. Collective memory forms the historical and epistemic basis for the conflict-based ideology, and this in turn influences how events related to the conflict are interpreted (Halperin & Pliskin, 2015). Such appraisals underlie the generation and regulation of emotions (Frijda, 1986), which subsequently lead to action tendencies and attitudes supporting or rejecting efforts for conflict resolution.

Consequently, emotions have been described as arguably the psychological fuel driving and escalating intractable conflicts (Halperin & Pliskin, 2015), since they guide attention to events, shape how events are then interpreted (Dukes et al., 2021), and determine attitudinal and behavioral responses. Research on emotions in the context of conflicts has indicated that they pervade both the antecedents and outcomes associated with conflicts (Lindner, 2006). Specifically, for intergroup conflict, group identification adds a layer of complexity to the role of emotions in conflicts and their resolution. Thus, the most relevant types of emotions to such contexts are group-based emotions and collective emotions.

In recent years, a combination of growing research regarding affective processes in psychology in general (Dukes et al., 2021; Ekman, 1999; Fredrickson, 1998; Frijda, 1986; Frijda & Mesquita, 1994; Keltner & Gross, 1999; Keltner & Haidt, 1999, 2001), and the acknowledgment of the importance in understanding emotions in political processes (Halperin & Pliskin, 2015; Mackie & Smith, 2015; Marcus et al., 2000), has led to a substantial increase in the study of emotions in intergroup, political conflicts (Cohen-Chen et al., 2020; Halperin, 2014, 2016; Halperin et al., 2011).

2.3.1. *Group-Based Emotional Phenomena*

Group-based emotions result from an individual's self-categorization as a member of a social group and occur in response to situations that have perceived relevance for that group (Goldenberg et al., 2016; Smith & Mackie, 2016). These emotions differ from the more classic individual emotions in that they are experienced by individuals merely as a result of their group membership. As such, people can experience group-based emotions "in the name" of their group, without even experiencing the emotion inducing event directly or personally. Importantly, group-based emotions are emotions that are experienced at the individual level. For example, an individual sitting on the couch may experience pride at the

sight of a representative of their country winning a medal in the Olympic Games, although they do not know the athlete personally, and have played no part in their success. The only thing they have in common is that they belong and identify with the same group (national, gender, or religious).

On the other hand, collective emotions (see Bar-Tal et al., 2007) are defined as macrolevel phenomena that emerge from emotional dynamics among individuals who are responding to the same situation (Goldenberg et al., 2020). As such, they represent emotional phenomena on the collective or group level, rather than on the individual one. Another example, again the context of the Olympics, is a widescale celebration in light of a substantial victory such as winning a gold medal. Here, a large number of people are experiencing pride or joy in light of the national achievement, and the emotion can therefore be considered a collective emotional experience.

3. RESEARCH APPROACHES TO EMOTIONS IN CONFLICT

Scrutinizing the recent developments in the study of emotions in conflicts in recent years, one can categorize that work into two very different, yet closely related categories. These two perspectives feed and inform one another mutually. The first perspective is descriptive and is characterized by scholars examining the role played by group-based and collective **emotional experience** in conflict situations. More specifically, most of the work in this area focuses on the way that discrete emotions, as well as other affective processes (e.g., emotional sentiments, clusters of emotions; Lazarus & Lazarus, 1994), shape policy preferences and other individual or group-based motivations in the context of intractable conflicts.

The second perspective is inspired by the Lewinian tradition (Lewin, 1943), according to which in order to really understand a phenomenon, one should attempt to change it. This approach, when applied to the study of emotions in conflict, can be described as interventionist due to its focus on ways **emotional change (or regulation)** can promote conciliatory attitudes and behaviors among parties involved in conflict. By deliberately inducing emotional change processes in conflicts, mostly using lab and field-based experimental designs, scholars contribute to the understanding of conflict resolution processes on the one hand, and to the more basic understanding regarding the nature, role, and implications of emotions in intractable conflicts on the other hand. Our chapter presents, for the first time, an integrative model bringing together both the descriptive and the interventionist approaches. This integrative model encapsulates both the role of emotional experiences in preserving and perpetuating conflicts, and the role of emotion regulation in potentially contributing to conflict resolution efforts and processes.

3.1. The Descriptive Approach—Emotional Experiences in Conflicts

The descriptive approach aims to understand and observe the role of emotions in conflicts, without seeking to intervene or change the emotional experiences themselves. Early work

on emotions in politics utilized a broad perspective based mainly on valence (the extent to which an emotion is experienced as pleasant or unpleasant) and its role in political behavior, or on the role of two distinct systems of clusters of emotions in these processes (Marcus, 2003). Over the years, scholars of emotions in conflict have found it more functional to refer to discrete emotions, which enables a more precise and specific examination of emotions and their corresponding behavioral tendencies. This approach draws upon appraisal theory of emotions (e.g., Ellsworth & Scherer, 2003; Frijda, 1986; see also Brader & Gadarian, Chapter 6, this volume), which delineates emotional processes as rooted in appraisals of meaningful events, leading to emotional goals and subsequently action tendencies. One major reason for this shift were consistent findings showing that emotions of the same valence and even the same intensity or arousal can lead to two very different, and sometimes even opposite political implications (e.g., Halperin et al., 2011; Lerner et al., 2003), which raised the need to develop a more precise scope of examination.

Accordingly, a conflict-related event relevant to an individual and associated group leads to an appraisal regarding the self or the ingroup, which elicits an emotional response, and subsequently a relevant attitude or behavioral tendency (Halperin, 2015). As Lindner (2006) outlines, emotions can (and should) be viewed simultaneously as both antecedents and outcomes of conflict, exacerbating the downward spiral so often described as the cycle of violence associated with intractable conflict (Coleman et al., 2007). In the current chapter, we refer to emotions in conflict using this integrative, cyclical approach, which sees emotional phenomena as both meaningful outcomes and powerful antecedents of political processes in conflict (Figure 30.1).

3.1.1. *Emotions as Outcomes*

Using this model to examine the role of emotional experiences in conflicts, two relationships have dominated the field (Lindner, 2006). The first examines ways in which conflict situations and events affect and influence emotions and emotional experiences (See Figure 30.1). The assumption is that conflict-related situations are meaningful enough to group members to draw their attention, influencing their appraisals of events or new information, and subsequently eliciting adaptive or maladaptive emotional reactions (Mackie & Smith, 2015) relevant to the conflict situation itself. The lion's share of research within the context of intractable conflicts has focused, understandably, on negative emotions.

As stated, the psychological infrastructure and culture of conflict shape how events are interpreted and therefore the emotional response to such events. Thus, the conflict ideology effectively constructs group based emotional reactions to the conflict. For instance, the perpetual threat posed by conflict situations, and the prevalence of these threats in the collective experience manifested in societal beliefs about security and victimhood within the ethos of conflict can lead to long term fear (Bar-Tal, 2001; Halperin, 2011; Jarymowicz

FIGURE 30.1 The descriptive approach

& Bar-Tal, 2006). Relatedly, threat content has been found to induce either fear or anger in low-power groups (Kamans et al., 2010). The unique existential characteristics of intractable conflicts have been found to elicit a feeling that the future of the group is in question, an appraisal underlying collective angst (Wohl et al., 2012). Similarly, intergroup anxiety stems from deep-rooted psychological and physical segregation between groups involved in such conflicts (Husnu & Crisp, 2010; Pettigrew & Tropp, 2006; Stephan & Stephan, 1985). However, threat has been found to elicit additional emotions, also related to the ingroup and its responses to events within the context of intractable conflict. Experiencing the inability to respond to an aggressive and unfair event or behavior perpetrated by the outgroup induces the emotion of humiliation (Fernandez et al.; Lindner, 2006, 2002; McCauley, 2017). On the other hand, guilt derives from feeling regret over the ingroup's harmful actions, coupled with appraised responsibility for the unfair or immoral misconduct toward an outgroup (e.g., Doosje et al., 1998).

Although not as prevalent, conflict-related events or new information may also elicit emotions that are experienced as positive for the individual. Events advancing the (imagined or real) possibility for peace in the future, as well as information increasing expectations of conflict resolution have been found to elicit the emotion of hope (Halperin et al., 2008; Leshem & Halperin, 2020; for a review see Cohen-Chen et al., 2017a). Another example is pride, experienced when an individual holds a positive group image, either in general or in a specific domain (de Figueiredo & Elkins, 2003; Schori-Eyal et al., 2015). These perceptions are also exhibited within the ethos of conflict, specifically societal beliefs about the ingroup's positive self-image as well as beliefs about peace (Bar-Tal & Halperin, 2013).

3.1.2. *Emotions as Antecedents*

The second relationship within the descriptive approach corresponds to the latter stage of the model (refer to Figure 1). Subsequent to the way in which conflict and conflict-related events induce emotional responses, a myriad of work examines the role that emotions play in eliciting conflict-related attitudes and behaviors (e.g., Bar-Tal et al., 2007; de Rivera & Paez, 2007). Each intergroup emotion has a unique story, stemming from its distinctive appraisal, emotional goals, and action tendencies. Previous research has examined the effect of similarly valenced or related emotions that may differ on a specific appraisal aspect. This difference may lead to differential attitudinal or behavioral tendencies in conflict. A notable example is anger and hatred, which are both negatively- emotions associated with aggression. However, while anger stems from an appraisal that the situation or group can be changed and efforts should be made to promote such change (Mackie et al., 2000), hatred is based in a perception of the outgroup as inherently evil and unchanging (Halperin, 2008). Importantly, although these two emotions often go hand in hand, this key difference between them has important implications and results in very different outcomes. For instance, anger in the absence of hatred was found to induce concessions in conflict (Halperin et al., 2011), and while anger motivated engagement in normative action, hatred induced violent action intentions (Shuman et al., 2016).

Moreover, each emotion has a discrete influence on attitudes and behavioral tendencies. This can be on individual level behaviors, such as engagement in collective action (*Hope*: Hasan-Aslih et al., 2020; *Anger*: Van Zomeren et al., 2000; *Anger/Hatred*: Shuman

et al., 2017; *Contempt*: Tausch et al., 2011), as well as support for policies or collective-level decision-making related to resolving intergroup conflict (Bar-Tal et al., 2007; Halperin et al., 2011, 2012). These unique effects of discrete group-level emotions on conflict related outcomes take place in different phases of intractable conflicts, as will be elaborated in the following pages.

3.2. Different Emotions Are Dominant during Different Phases

Group-level emotions play a significant role in all phases of intractable conflicts, yet, research in recent decades suggest that different emotions play different roles in different phases, although some emotions are dominant in more than one phase. For the sake of simplicity, we now focus on the most dominant emotional processes, characterizing each phase.

Conflict eruption, as the starting phase of any intractable conflict, a process in which the parties' conflicting goals rise above the surface and spark the potential for violent intergroup confrontation. Intractable conflicts erupt over goals that are perceived to be of existential importance and often are related to core beliefs associated with group identity. They are based on severe grievances and contentions that are accompanied by strong emotional feelings (Coutant et al., 2011; Kriesberg, 2007). Azar (1990) suggested that the basic conditions for eruption of protracted conflicts are deprivation of basic needs related to collective identity (see also Brewer, 2011; Kelman, 1997; Korostelina, 2006; Reicher, 2004; Staub, 2011). The eruption process is driven by intra as well as inter-group processes that stimulate and motivate the destructive transformation of the disagreements into overt and active conflict. The challenge of mobilizing society members to actively participate in the intractable conflict is of crucial importance. Many of the ideas related to the psychological processes that underlie collective action (see: van Zomeren et al., 2008) can be applied to mobilization for conflict.

The emotion that has been most frequently studied with respect to this stage of the conflict is anger. *Anger* is evoked by events in which the individual perceives the actions of others as unjust, unfair or as deviating from acceptable societal norms (Averill, 1983). In addition, it involves appraisals of relative strength and high coping potential (Mackie et al., 2000). The integration of these two characteristics often creates a tendency to confront (Berkowitz, 1993; Mackie et al., 2000), strike, kill, or attack the anger-eliciting target.

In line with its characteristics, previous studies conducted in the context of real-world conflicts have consistently found a clear and direct association between anger and the attribution of blame to the outgroup (Halperin, 2008; Small et al., 2006). Other studies have found that individuals who feel angry appraise future military attacks as less risky (Lerner & Keltner, 2001) and anticipate more positive consequences for such attacks (Huddy et al., 2007). Accordingly, studies conducted in the United States following the September 11 attacks found that angry individuals were highly supportive of an American military response in Iraq and elsewhere (e.g., Huddy et al., 2007; Lerner et al., 2003; Skitka et al., 2006). Finally, the central role of group-based anger in motivating conflict eruption and aggression yielded further support in a recent study conducted in Serbia and Republika Srpska (Spanovic et al., 2010).

Humiliation is another important emotion that appears in the early phase of conflict eruption. It is a particularly strong aversive self-conscious emotion that arises when a person or a group see themselves as unfairly demeaned, degraded, or put down (Elshout et al., 2017; Fernández et al., 2015; Lindner, 2006; McCauley, 2017). The experience of humiliation has been associated with particularly negative outcomes for the psychological well-being of the victims, such as major depression, severe anxiety, or suicidal tendencies (Hartling & Lindner, 2016; Klein, 1991; Torres & Bergner, 2012). Not in vain, humiliation has been labeled the “nuclear bomb of emotions” (Lindner, 2006, p. xiii) to emphasize its extreme destructive outcomes. It creates rifts between groups and breaks relationships (Lindner, 2001). This feeling arises in many of the conflict situations in which societies experience deprivation as a result of discrimination, oppression, and/or exploitation. Humiliation often creates a motivation to retaliate, as the humiliated group sees it as the only way to regain positive group identity and image.

Conflict escalation and management entail strategies to contend with conflict while it is expected to continue, including choices about how to respond to violence, as well as how to treat civilians and civilian causes among the adversary. Escalation indicates that the grievances, objections, and contentions raised are not met with understanding and compliance, but rather with dismay, rejection, and even stronger counter-actions. Consequently, the party that raised the grievances or objections resorts to harsher steps, in order to make the conflict more salient and more costly to the rival. These steps are met with severe reactions, and both sides thus raise the level of confrontation, entering into cycles of reactions and counter reactions (Horowitz, 1985; Kriesberg, 2007). From a psychological perspective, our assumption is that conflict escalate due to a destructive feedback loop between the actual context and events on the one hand, and the psychological repertoire, held by society members, on the other hand. The psychological repertoire leads to actions that escalate the conflict, in turn the escalation reinforces the repertoire that perpetuates the conflict, due to the dominance of the culture of conflict and its bearing on collective identity.

Two dominant emotions that have received much attention in the current literature as impacting policy preferences in this context are fear and anger. Fear is associated with the appraisal that one is under threat and lacks sufficient strength or control to overcome the threat—and is characterized by the motivation to defend and protect oneself (Roseman et al., 1994; see Stein for a discussion of fear and perceived threat, Chapter 11, this volume). These lead to action tendencies focused on minimizing risk, which may take the form of either “fight” or “flight” depending on what seems most effective for threat reduction. Indeed, while in some violent conflicts fear has been found to decrease support for military action (e.g. Huddy et al., 2007; Skitka et al., 2006), in more intractable conflict, where “flight” seems less possible, fear leads to defensive aggression increasing support for aggression toward the outgroup (e.g. Spanovic et al., 2010; Stein, Chapter 11, this volume).

Anger, as mentioned above, is associated with appraising the outgroup’s behavior as unjust and the ingroup as strong and able to successfully contend with risk and confrontation with the other (Smith et al., 2007). Anger is further associated with the motivational goal of taking action and setting right the outgroup’s perceived wrongdoing (e.g., Roseman et al., 1994). Correspondingly, in the context of conflict management and escalation, anger most often leads to justification of and support for confrontation and use of violence against the outgroup (e.g., Huddy et al., 2007; Pliskin et al., 2014; Halperin et al., 2013; Skitka et al., 2006).

De-escalation and peacemaking: Although de-escalation of intractable conflicts is a highly difficult challenge, almost every society engaged in such conflict contains societal forces (even that they are a small minority) that propagate and press for embarking on a different road—the road of peacemaking. Once these forces grow and become influential, it is possible to say that the process of peace-building has gained momentum. In some societies, this process even ends with a peaceful settlement following negotiations that may extend over many years (see Fisher et al., 2013). People living under long-term conflict often acknowledge that dramatic compromises are necessary for the promotion of peace yet often do not endorse them. Emotions modulate such support, with some emotions presenting a barrier and others facilitating it.

One of the most powerful emotional barriers to de-escalation and peacemaking is that of hate. Hatred is driven by the appraisal that the outgroup is inherently and unchangeably evil, thus people who are dominated by hate unequivocally reject any compromise toward changing relations between the groups because it is deemed futile (Halperin, 2008, 2011). The impact of anger and fear for conflict resolution is more complex in that they may drive either opposition or support for political compromise depending on how such compromise is construed. The appraisals of anger, namely, seeing the outgroup as unjust and the ingroup as strong and able to successfully contend with risk (Smith et al., 2007), often leads to opposition to compromise (e.g., Huddy et al., 2007; Skitka et al., 2006; Spanovic et al., 2010). However, when correction of outgroup wrongdoing is deemed possible through conciliatory action (for example, if education and mass media campaigns are perceived effective in inducing change in outgroup behavior), anger can increase support for compromise (Halperin et al., 2011; Reifen-Tagar et al., 2011).

Fear (and by extension, anxiety or angst), on the other hand—given that it is shaped by the appraisal that the magnitude of threat is greater than one's ability to overcome it, and characterized by the motivation to avoid risk and restore security—often presents a meaningful barrier to support for conciliatory policies (Bar-Tal, 2013; Bar-Tal & Halperin, 2011; Sabucedo et al., 2011), as they are perceived as potentially risky, or at the very least as uncertainty inducers. However, to the extent that compromise can be construed as the path to establish security, fear is likely to increase willingness to compromise (Halperin et al., 2013; Spanovic et al., 2010).

Finally, hope, an emotion characterized by positive affect coupled with an expectation for further positive outcomes, is a meaningful facilitator of conflict resolution. Hope increases openness to and active search for new information (Bar-Tal, 2013; Cohen-Chen et al., 2014), and increases creative thinking about solutions, and support for compromises (Cohen-Chen et al., 2015; Cohen-Chen et al., 2014a; Leshem et al., 2016).

A further important force relevant for de-escalation and peacemaking is engagement in collective action, such as participation in demonstrations or signing petitions, to advocate for or oppose conciliation or compromise (van Stekelenberg & Gaidyte, Chapter 26, this volume). Anger has been identified as the most relevant emotion motivating collective action (Tausch et al., 2011; van Zomeren et al., 2012). To a lesser degree, guilt also motivates participation in collective action in support specifically of reparations to the outgroup for harm caused by the ingroup (Mallett et al., 2008; Solak et al., 2017). Hope has also been proposed as a meaningful predictor of collective action, stemming from its goal-driven action-orientation and the belief in the possibility of a brighter reality (Cohen-Chen et al.; Greenaway et al., 2016).

Reconciliation goes beyond the formal resolution of the conflict by focusing on steps to address the psychological needs of the sides and to transform their relationship—such as acknowledgment of and support for compensation of past outgroup suffering, willingness to extend apologies, and to accept them and forgive. A dominant emotion shaping people's willingness to acknowledge and compensate outgroup suffering is guilt. Group-based guilt stems from appraisals of ingroup responsibility for illegitimate harm to the outgroup (Doosje et al., 1998; Ferguson & Branscombe, 2014) and is associated with the motivation to correct the wrongdoing, and to be forgiven by the outgroup. Group-based guilt has been found to increase support for compensation across different conflicts (e.g., Allpress et al., 2010; Čehajić-Clancy et al., 2011; Lickel et al., 2011), and is also associated with support for the extension of official apologies to the outgroup for past moral transgressions (Leonard et al., 2015; McGarty et al., 2005).

Another relevant self-targeted emotion stemming from the appraisal of responsibility for harm inflicted on others is shame. However, unlike guilt, it is coupled with the appraisal that the wrongdoing is indicative of the perpetrator's defective nature (Tangney, 1991). Correspondingly, shame is characterized by the motivational goal of validating the ingroup's image (Allpress et al., 2010; Brown et al., 2008). Hence, in the context of reconciliation, shame has been found to increase both support for reparations and defensive avoidance (Allpress et al., 2010; Brown & Čehajić, 2008; Lickel et al., 2005), likely depending on the extent to which the damaged group-image is deemed reparable (Leach & Cidam, 2015).

Finally, empathy—the experience of a congruent emotion to that of another—plays an important role in reconciliation, especially in how recipients of intergroup apologies respond to it. Consistent with empathy's motivational goal of alleviating the discomfort or suffering of the other (Cikara et al., 2011), several studies have found that empathy is associated with willingness to forgive the opponent for past transgressions (e.g., Čehajić et al., 2008; Tam et al., 2008).

3.3. “Feel Good”/“Do Good”: An Alternative Perspective to the Role of Emotions in Conflicts

One way to look at the role played by group-level emotions in conflict, as presented above, is to examine emotional impact in each and every phase of the conflict. A more nuanced way to look at the very same phenomenon was recently offered by Cohen-Chen and colleagues (Cohen-Chen et al., 2020), who introduced a framework categorizing emotions according to two separate dimensions: valence (the extent to which emotions are experienced as pleasant or unpleasant) and function (the extent to which emotions lead to outcomes supporting or hindering conflict resolution). This differentiation is particularly important in intractable conflicts, in which clashes between how good an emotion feels and the good that it does in terms of the conflict more broadly are very prevalent. Importantly, the position of each emotion in a specific quadrant is dynamic and subject to change, dependent on contextual factors such as power or (Cohen-Chen et al., 2020). For example, anger may be experienced as pleasant when feelings of empowerment are emphasized (Lerner & Tiedens, 2006), while hope for intergroup harmony may diminish motivation to change power

asymmetries when induced in a low-power group (Hasan-Aslih et al., 2020). However, that is beyond the scope of this chapter.

Feel bad/do bad emotions are emotions that involve negative affect for the individual, and simultaneously induce conflict-escalating attitudes and behaviors. This definition encompasses within it the largest number of emotions, due to the very nature of conflict as harmful and destructive. For example, hatred (Fischer et al., 2018; Opatow & McClelland, 2007; Sternberg, 2005) is a negatively valenced emotion stemming from an appraisal of the outgroup as holding a stable and evil nature (Halperin, 2008). Subsequently, hatred has been found to lead to aspirations of annihilation of the outgroup as a whole, triggering extreme intergroup aggression (Halperin, 2008). Similarly, humiliation, an emotion based on an internalization of aggressive external message that is perceived to be hostile but unjust (Fernandez et al., 2015; Lindner, 2006; McCauley, 2017), has been suggested to predict reactive violence and aggression (Lindner, 2006; Motyl et al., 2009), as well as diminishing support for opportunities to achieve peace (Ginges & Atran, 2008). Lastly, emotions elicited by a sense of threat to the ingroup, such as intergroup anxiety (Brown & Hewstone, 2005; Halperin et al., 2012) and fear (Halperin et al., 2008; Pliskin et al., 2015) have been found to increase avoidant behaviors, diminishing willingness to engage with the outgroup to promote conflict resolution. Fear in conflict has been found to induce cognitive freezing (Kruglanski, 2004), leading to a focus on threatening information (Cohen-Chen et al., 2014) and preventing openness to new ideas (Clore et al., 1994; LeDoux, 1995).

Feel bad/do good emotions are those which are experienced as negative or unpleasant, but induce peace-supporting attitudes or behaviors. An example that has gained much interest and evidence is guilt, which is experienced as negative based on an appraisal of being personally accountable or seeing the ingroup as responsible for negative and unjust acts aimed at the outgroup (Branscombe et al., 2004). Despite the negative experience associated with the emotion, guilt has been shown to encourage support for reparations or apologies for past wrongdoing (Brown & Cehajic, 2008; Brown et al., 2008; Iyer et al., 2003; McGarty et al., 2005), promoting intergroup conciliation. Another emotion that may feel unpleasant but has been found to promote positive intergroup attitudes is sadness, associated with an appraisal of significant loss (Camras & Allison, 1989). Gur, Ayal, and Halperin (2021) recently showed that experiencing sadness can reduce political polarization and promote peace-supporting attitudes. Lastly, collective angst (Wohl & Branscombe, 2008) is a negative emotion experienced when group members appraise their group as under existential threat. However, collective angst has been found to induce attempts to prevent the negative outcome, which can at times manifest in promoting conciliatory attitudes (Wohl et al., 2016; Halperin et al., 2013).

Although not considered a discrete emotion, empathy (Batson & Shaw, 1991; Cikara et al., 2011; Decety & Jackson, 2004; Zaki, 2019) is characterized by feelings of sympathy and compassion toward a suffering or misfortunate (member of the) outgroup (Hasson et al., 2018) and therefore is categorized as negatively valenced. Empathy is linked to cooperation in interpersonal and intergroup attitudes (Batson & Moran, 1999; Eisenberg & Miller, 1987), and in the context of intractable conflicts has been found to induce support for humanitarian policies to help the outgroup (Balmas & Halperin, 2021; Pliskin et al., 2014; Rosler et al., 2017). Due to both its valence and its behavioral outcomes, members of group are motivated not to experience empathy, which makes it uncommon in the context of intractable and violent conflicts.

As previously mentioned, positively valenced emotions are significantly less prevalent in the context of violent and extreme conflicts. However, they too can have opposite effects on conflict-related attitudes (Cohen-Chen et al., 2020). Emotions that are experienced as pleasant, or the contextual conditions that may change the emotional valence (such as sadness enhancing a feeling of togetherness; Porat et al., 2016; Porat et al., 2016), emphasize the importance of emotional preferences and the motivation individuals have to experience certain emotions (Tamir, 2016).

Feel good/do bad emotions are emotions experienced as positive or pleasant, but induce conflict-exacerbating attitudes. A notable example is pride. Despite being experienced as elevated and positive due to the achievements or nature of the ingroup (Sullivan, 2007), pride has been found to be associated with increased aggression (Baumeister, 2001), prejudice against outgroup members (Pettigrew, 1997), and hostility toward outgroup members via increased nationalism (de Figueiredo & Elkins, 2003).

Lastly, *feel good/do good* emotions are those which both feel pleasant and promote intergroup harmony. The most notable example is the emotion of hope, which, as previously mentioned, is a positively valenced emotion elicited in light of imagining a positive and desired goal in the future (Lazarus, 1999; Cohen-Chen et al., 2017b; Leshem & Halperin, 2020). Long-term hope has been found to have positive associations with a myriad of peace-supporting attitudes, such as favorable information processing (Cohen-Chen et al., 2014), support for humanitarian aid to the outgroup (Halperin & Gross, 2011), support for conciliatory attitudes (Halperin et al., 2008; Cohen-Chen et al., 2019), and openness to engaging with the outgroup (Saguy & Halperin, 2014). Notably, and as previously stated, hope can, under some conditions, elicit outcomes detrimental to conflict facilitation (Hasan-Aslih et al., 2020). However, this is beyond the purview of this chapter.

As aforementioned, we refer to the interplay between the conflict and the emotional experiences in the conflict as a cyclical process (see Figure 1). One example of such a process might begin with an initial conflict related event (Lindner, 2006), which violates the ingroup's sense of justice, the underlying appraisal associated with the emotion of anger (Averill, 1983). As stated, anger has been found to increase aggressive attitudes (Skitka et al., 2006), which in intractable conflict contexts is translated into support for aggressive policies against the outgroup. As this process progresses and repeats itself, this continuous cycle may expand and become ingrained in collective memory and narrative (Bar-Tal & Halperin, 2011). As parties involved continue to act and react, leading perceptions of the outgroup as inherently evil (underlying the emotion of hatred and further inducing extreme violence and aspirations to annihilate the outgroup; Halperin, 2008), and the conflict as fundamentally irresolvable, feeding into the hopelessness (Jarymowicz & Bar-Tal, 2006) that perpetuates the conflict. As the cycle intensifies, different perceptions come into play, triggering new appraisals and therefore a variety of emotions.

3.4. The Interventionist Approach—Emotion Regulation in Intractable Conflict

For many years, social scientists have endeavored to understand the creation, preservation, escalation, and resolution of intergroup conflicts with the aim to develop interventions for promoting peace and intergroup harmony (Lewin, 1943). This includes a myriad of

approaches from many fields and schools of thought, which have proven efficacious, as presented below. Nonetheless, these approaches' success has been found to be limited in extreme, protracted conflict situations. Recently, and as mentioned above, emotions have captured the attention of social psychologists as a key mechanism underlying political attitudes, perceptions, and behavior in contexts characterized by extreme animosity. Subsequently, this approach has become a central avenue in creating and developing interventions aimed at engendering reconciliation.

3.4.1. *Classic Interventions Promoting Intergroup Harmony*

Arguably the most famous and well-researched contribution to reducing intergroup conflict has been *Contact Theory* (Allport, 1954; Barlow et al., 2012; Dhont & Van Hiel, 2009; Graf et al., 2014; Hayward et al., 2017; Pettigrew, 2008; Pettigrew & Tropp, 2006; Tropp, 2021; Tropp & Dehrone, Chapter 29, this volume). Contact theory posits that, under certain conditions, contact between members of different social groups can reduce intergroup bias (Allport, 1954). Members of opposing or different groups should be of equal status to one another and should cooperate to achieve common goals. Moreover, integration and contact should be supported by authorities and group norms, or attitude change will be difficult to achieve (for a meta-analysis see Pettigrew & Tropp, 2006).

These conditions are often impossible to achieve in highly charged, extremely segregated contexts such as intractable conflicts. Counter-productive consequences have been said to be caused by defensive reactions to meeting and "fraternizing" with the enemy (Bar-Tal & Rosen, 2009; Bekerman & Maoz, 2005), leading to deterioration of intergroup relations. Within the Israeli-Palestinian conflict, contact theory, in certain forms, has been shown to be ineffectual. At times contact theory has even been described as immoral by preserving the status quo (Maoz, 2011; Maoz et al., 2007). In the case of asymmetrical relations between groups, contact-based interventions that do produce positive perceptions of the outgroup lessen perceptions of existing power differences (Saguy & Chernyak-Hai, 2012; Saguy et al., 2009).

Over time, contact-based interventions were developed in order to overcome physical, language-based, and cultural segregation (Crisp & Turner, 2009; Pettigrew, 2008), as well as low motivation to engage in actual contact due to anxiety, discomfort, or bias (Crisp & Turner, 2009; Dixon et al., 2005; Wright et al., 1997). Based on this, interventions began to move away from direct interactions between outgroup members, while maintaining a focus upon the specific outgroup in question. *Extended Contact* (Wright et al., 1997; Turner et al., 2008), demonstrating that knowledge of a close relationship between an ingroup member and an outgroup member can improve intergroup attitudes. Later on, *Imagined Contact* (Crisp et al., 2008; Crisp & Turner, 2009) used mental simulations to change attitudes toward an outgroup, by providing a "safe" way for people to engage in contact with the outgroup, and reducing intergroup anxiety (Birtel & Crisp, 2012; Stathi et al., 2012; Turner et al., 2007).

Another approach, based on social identity theory (Tajfel & Turner, 1979), is the *Common Ingroup Identity Model* (Gaertner & Dovidio, 2000). This approach focuses on creating a common identity, shared by members of different groups, to reduce bias and stereotyping. *Decategorization* highlights individual identity over group identity (Bettencourt et al., 1992), *recategorization* highlights a superordinate or shared identity of outgroup members

(Gaertner & Dovidio, 2000). Relatedly, *crossed categorization* (Crisp & Hewstone, 2000) blurs intergroup boundaries by highlighting shared social categories.

Although traditional interventions for promoting intergroup relations have proven successful in a large number of contexts, the understanding has gradually emerged that in intractable conflicts, one of the major fuels of the conflict, emotions, has been overlooked by classic approaches in working to instill peace and intergroup harmony. Zero-sum perceptions make common goals nearly impossible (Brewer, 1999; Hornsey & Hogg, 1999). A collective narrative and socio-psychological infrastructure endorses and sustains the conflict, rather than supporting prejudice-reducing activities and interventions (Bar-Tal, 2000; Bar-Tal & Rosen, 2009). Consequently, attempts to change these mutually and deeply engrained norms come up against reactance, as they are interpreted as a threat to the group's identity and existence (Bar-Tal, 2007). Emotions, as flexible mechanisms associated with cognitions, identity, and motivations, are a key psychological mechanism in reconciliation processes, playing a pivotal role for intergroup relations characterized by rigid attitudes and perceptions. Thus, without addressing the emotional aspect underlying political attitudes and motivations, change, and particularly consistent and long-term change, is extremely difficult to achieve (Cehajic-Clancy et al., 2016).

3.4.2. *Emotional Interventions—The Age of Affectivism*

In recent decades, following similar trends in other domains within psychological sciences, political psychologists have shown an increasing shift from a descriptive to a more interventionist approach. This shift is manifested in work focusing on offering evidence-based interventions to reduce intergroup prejudice and promote intergroup reconciliation (see: Hameiri et al., 2014; Paluck et al., 2020). Specifically, regarding the study of emotions in conflict, while the descriptive approach serves the initial purpose of furthering knowledge regarding the role of emotions in conflict, it stops short of expounding how this information can be used to change this harmful spiral of conflict.

Accordingly, emerging research has aimed to understand how this knowledge can be used to *change* emotions in order to promote attitudes for conflict resolution (Halperin, 2015; Halperin et al., 2014; Halperin & Pliskin, 2015). This line of work utilizes knowledge regarding the role of emotions in conflict, as well as extant research on emotion regulation (Gross, 1998, 2007), which refers to the process of influencing emotional responses by the self or others. In the context of intractable conflict, work on emotion regulation investigates ways in which emotions elicited by conflict-related events can be changed, leading to subsequent attitudinal and behavioral changes (for recent reviews see: Gross et al., 2013; Halperin & Riefen-Tagar, 2017).

3.4.2.1. *Emotion Regulation* The idea that even powerful emotions can be modified is the cornerstone of a rapidly developing field of research in affective science that is concerned with emotion regulation, defined as the processes that influence which emotions we have, when we have them, and how we experience and express them (Gross, 2014). Because emotions are multi-componential processes that unfold over time, emotion regulation may involve changes in various components of the emotional process, including the latency, rise time, magnitude, duration, or offset of responses in behavioral, experiential, or physiological domains (Gross & Thompson, 2006). Emotion regulation may increase or decrease the

intensity and/or duration of either negative or positive emotions, and the defining feature of emotion regulation is the activation of a goal to modify emotion generation (Sheppes & Gross, 2011). Most of the research on emotion regulation has thus far focused on individuals or dyads. However, many of the insights from such research are applicable to intergroup conflicts (Goldenberg et al., 2016, 2020).

Emotion regulation pertains both to situations in which people regulate their own emotions as well as to processes through which individuals or groups regulate others' emotions. In terms of the change strategy itself, one way to categorize emotion regulation processes is to examine not the target (the individual whose emotion is changing) but the process of the regulation. This results in two different approaches to emotion regulation—a direct approach (people are directly asked or trained to regulate their emotions) and an indirect approach (messages are conveyed to indirectly regulate other's emotions). These two approaches and the differentiation between them are particularly relevant in the context of intractable conflicts, in which emotions should be regulated in masses, people are not always motivated to down-regulate their negative emotions, and the source of the individual or group that aspire to stimulate the emotion regulation process is critical in determining its effectiveness.

3.4.2.2. *Direct Emotion Regulation* Emotion regulation in its direct meaning refers to self-driven, intentional efforts to change the intensity, valence, or type of experienced emotion (Gross, 1998, 2007). People can regulate their own emotions and attempt to regulate the emotions of others. This may be targeted toward positive, as well as negative, emotions, assuming the form of upward (increasing levels of arousal) or downward (decreasing levels of arousal) regulation. In what now is already considered as the classic model of emotion regulation, James Gross (1998) offered five main strategies of direct emotion regulation that follow the process and sequence of the way emotions evolve—situation selection, situation modification, attention deployment, cognitive change, and response modulation.

All these direct emotion regulation strategies can be applied, with some necessary adjustments, to the realm of intergroup conflicts and to the regulation of group-level emotions (Goldenberg et al., 2016). The required adjustments are mostly impacted by the collectivistic nature of the emotional experience, by the central role played by social identities in these contexts, as well as from the fact that the actual experience of the emotion often takes place in a crowded or at least subjectively “groupy” environment. Also, the question of what is actually needed to regulate the emotions of a group, and in what way is it different from simultaneous regulation of many individual emotions, is still unresolved.

In terms of empirical support for the effectiveness of direct emotion regulation strategies within the context of intractable conflict, one strategy that has received substantial attention is cognitive reappraisal—the modification of meaning-giving to different situations aimed at shifting one's emotional reactions to them. In one example (Halperin et al., 2013) researchers trained participants in the skills of cognitive reappraisal (unrelated to the context of conflict), and compared those participants' emotional and political reactions to those of a control group. Equipped with the skills of cognitive reappraisal, participants reacted with less anger to a real political anger-inducing event, leading them to demonstrate greater support for conciliatory policies, both one week and five months after training. Same pattern of results was received in another study in which the ultimate political outcome of

the emotion regulation intervention has been reduced political intolerance toward conflict related outgroups (Halperin et al., 2013). A similar pattern of results was obtained recently in a less intense intergroup conflict, when two direct emotion regulation strategies, cognitive reappraisal and suppression, led to increased intergroup openness among a sample of Finnish participants (Westerlund et al., 2020). Finally, in a recent study, results regarding the constructive implications of reappraisal were observed also using reappraisal training through smartphone application, rather than through in-lab, face-to-face training (Porat et al., 2020). Clearly, training in emotion regulation skills can enhance peace-oriented reaction to political events. The challenge with training in direct emotion regulation, however, is that it hinges on people's motivation to regulate their emotions in a direction conducive to peace promotion, which, especially in the context of intractable conflict, is often not the case.

Therefore, another configuration of direct emotion regulation in the context of intergroup conflicts focuses on deliberative attempts to change people's motivation to experience or not to experience certain emotions, rather than on the emotion-regulation skills required in order to do that (Porat, Tamir & Halperin, 2020). Change in motivation to experience certain emotions can be done by highlighting either hedonic or instrumental considerations or benefits, or some integration of both. Recent attempts to regulate conflict-related emotion through altering motivation were successful, when across four studies, Porat and colleagues (Porat et al., 2016) were able to alter group-based emotional experiences, and even political reactions, simply by changing what people wanted to feel. Specifically, Jewish-Israelis actively down-regulated anger or fear when they were led to believe that the experience of these emotions toward Palestinians might impair their political decision making (Porat et al., 2016).

3.4.2.3. Indirect Emotion Regulation Despite the success garnered by the direct approach to emotion regulation, the context of intractable conflict poses a unique challenge in the application and widespread utilization of direct emotion regulation. The notion that people involved in deeply entrenched conflicts are motivated to down-regulate negative emotions or up-regulate positive emotions has been described as widely misplaced (Tamir, 2009). On the contrary, many of the beliefs that form the underlying appraisals of such emotions are exacerbated by the collective narrative (Bar-Tal, 2001; Bar-Tal & Rosen, 2009), which serves as a survival mechanism for groups involved in intractable conflicts. Relatedly, recent work has pointed to a misalignment between the valence and functionality of emotions in conflicts (Cohen-Chen et al., 2020). As aforementioned, this work suggests that in conflicts, and particularly intractable conflicts, emotions that are experienced as positive for the individual (such as ingroup pride; Averill, 1983; Baumeister, 2001; de Figueiredo & Elkins, 2003) are often detrimental to the resolution of conflict, while emotions experienced as negatively valenced (such as guilt or empathy; Wohl et al., 2006) can be functional to resolution efforts.

This disaccord further upholds the need for indirect interventions in promoting peace-making attitudes through emotions, manifested as indirect emotion regulation (for a review see Halperin et al., 2014). One notable advantage of the indirect approach is the fact that it bypasses the necessity for individuals to be motivated to regulate their emotions (Halperin et al., 2014). The process begins with associating between a target conflict-related action tendency and the connected discrete emotion. Next, core appraisal themes underlying

the emotions (Roseman, 1984; Scherer, 1984) are identified, and various strategies and interventions are employed to change those appraisals without necessarily mentioning the outgroup or the context of the conflict. While we present a number of examples, this by no means is an exhaustive review, as more examples of indirect emotion regulation can be found in the literature.

One such strategy addresses general beliefs or perceptions, which individuals then apply deductively to the specific context subconsciously. A substantial amount of work employing this approach has utilized the well-established implicit theories (Chiu et al., 1997; Chiu et al., 1997; Dweck et al., 1995) according to which people hold beliefs regarding the malleability of various constructs, such as individuals (Plaks et al., 2001), and groups (Rydell et al., 2007). Research within the interventionist approach has utilized strategies based on implicit theories for two reasons. First, malleability beliefs are relatively simple to change (Blackwell et al., 2007; Heslin et al., 2005). Second, malleability is associated with a number of emotions' core appraisal themes. One example is hatred, which is based on the appraisal of the outgroup as inherently and unchangeably evil (Halperin, 2008). Interventionist research that sought to regulate hatred indirectly imparted the belief that groups in general are malleable, without referring to the outgroup in question. This relatively simple, applicable, and indirect intervention successfully reduced intergroup hatred and increased support for concessions within the context of the Israeli-Palestinian conflict (Halperin et al., 2011). A related design addressed hopelessness, which is rooted in the appraisal of the conflict as irresolvable (Jarymowicz & Bar-Tal, 2006). Applying a similar approach further led to interventions that instilled general malleability of groups (Goldenberg et al., 2018), conflicts (Cohen-Chen et al., 2014), and the world (Cohen-Chen et al., 2015). Although the specific conflict and outgroup were never mentioned directly, these interventions successfully induced hope for peace and subsequently support for conciliatory policies in intractable conflict.

A further indirect strategy does not depend on deductive reasoning (all groups are malleable therefore the outgroup is malleable) but addresses an unrelated psychological need that would enable acceptance of an idea or message underlying an emotion functional for conflict resolution (Cohen-Chen et al., 2020). One such example is group-based guilt (Branscombe et al., 2004), which induces support for reparations or apologies (Brown & Cehajic, 2008; Brown et al., 2008; Iyer et al., 2003; McGarty et al., 2005). Guilt is elicited by an appraisal of an unjust or immoral act perpetrated by an individual's ingroup toward an outgroup. The acceptance of ingroup responsibility is however in stark contrast to the ethos of conflict (Bar-Tal, 2001), which asserts ingroup righteousness and poses a threat to the need for a positive ingroup image (Tajfel & Turner, 1979). One line of work (Čehajić et al., 2011) addressed this need by administering a self-affirmation intervention, which enables group members to tolerate a threat to a specific aspect of their identity, in the form of responsibility acceptance, if they are able to affirm other aspects of their ingroup image. Results showed that without referring to the conflict, the self-affirmation intervention successfully led to increased guilt, subsequently leading to support for reparations to the outgroup in conflict. Across these examples, by addressing a seemingly unrelated belief or psychological need, the context-specific appraisal was influenced when the event or new information is introduced, which subsequently up-regulated or down-regulated the relevant emotion.

3.5. The Integrative Model: Emotions and Emotion Regulation in Conflict

Integrating the descriptive and the interventionist approaches, we contend that each type of intervention corresponds to a different stage in the emotion-elicitation process, creating a comprehensive model of emotions and emotion regulation in conflict (Figure 30.2).

The *indirect approach* corresponds to the stage in which conflict-related events elicit emotions in conflict. This is because such interventions transform the way events, behaviors, and relationships are appraised, changing the way emotions are experienced. Indeed, this approach essentially targets the appraisal tendencies (Lerner & Keltner, 2000, 2001) rather than an already formed appraisal, which lead to the formulation of the appraisal itself (Halperin et al., 2014). The fact that the indirect approach does not tackle specific conflict-related content or attitudes means that changes in general or unrelated perceptions could potentially be applied to other contexts entirely (or not at all) and is therefore not content-specific to the conflict.

Advantageously, the fact that the indirect approach focuses on the relationship between a conflict-related event and the emotional experience means that the regulation process comes into play before the appraisal and destructive emotion are even formed. Gross (2008) refers to this stage as taking place when the event in the emotion generative process cannot be modified by the individual, but before the event is imbued with a specific meaning. At this point, the individual (or an external party) may take specific actions (attentional deployment; Gross, 2008) to affect how this event is interpreted and becomes the appraisal in question. Applied to the context of conflict, rather than the individual choosing to change appraisal tendencies affecting how an appraisal is formed, the intervention itself (externally administered) changes how conflict-related events are interpreted and therefore how appraisals are formed.

This is meaningful because previous work has established that over time recurring (negative) experiences become entrenched in psychological schema and grow more automatic, persistent, and stable (Eagly & Chaiken, 2005; Frijda et al., 1991). Such long-term sentiments in conflict then exacerbate corresponding emotional responses by biasing the cognitive

FIGURE 30.2 An integrative model of emotions and emotion regulation in conflict

appraisals of an event (Halperin & Gross, 2010). Based on this logic, changing the process by which an event is appraised negatively before it is actually formed would alleviate and weaken this inevitable and destructive association. Previous research has shown that the frequent application of such interventions creates the effect's endurance over time (Yeager & Walton, 2011). It therefore stands to reason that this approach could change *the way* in which events or new information are interpreted and processed in the first place, leading to long-term change in intergroup attitudes through intergroup emotions.

On the other hand, the direct approach corresponds to the second stage, in which emotions are antecedents of political outcomes. This is because direct emotion regulation, and particularly the most common form of it, cognitive reappraisal (Gross, 2007), operates mostly after the emotion has already appeared. Here, the assumption is that the appraisal has already been formed (based on previous experience and long-term emotions), and the emotion is already being experienced by the individual. In that case, the reappraisal process intervenes at the point in which the action tendencies associated with the discrete group-level emotion are just about to transform into a concrete conflict related motivation, behavioral tendencies, or policy preferences. Naturally, changing emotions after they have already been formed is a challenging task, but research have demonstrated that emotion regulation strategies can be effective, even at that point of the emotional process. Moreover, regulating emotions after they have emerged can be even more important when it comes to group-level emotions and to intractable conflicts. This is especially true in these cases because emotional reactions in groups might have a diffused and amplifying nature (see Goldenberg et al., 2016, 2020), so down-regulation negative emotions among some members of the group can be effective in preventing escalation of the emotional experience among the group in general.

4. CONCLUSIONS AND FUTURE DIRECTIONS

A recent consensus paper, written by dozens of leading scholars of emotions and affective sciences, has recently raised the question of whether social sciences are now moving into the era of what they defined as "Affectivism" (See Dukes et al., 2021). In the final paragraph of that paper, the authors state that "the conceptual, methodological and technical advances made within the last few decades have demonstrated that affective processes are unquestionably enlightening when it comes to understanding both behavior and cognition. While it will ultimately be the responsibility of historians of science to determine whether or not a new era has begun, given the undeniable impact of affective sciences on our models of brain, mind, and behavior, it seems relevant to ask today whether we are now in the era of 'affectivism'" (Dukes et al., 2021, p. 5).

We argue that although the scientific work on the role of emotions and emotion regulation processes in intergroup conflicts has developed rapidly in the last two decades, it is still in its early stages. The dominance of affective processes in this area of research is not yet close to the description in the previous paragraph regarding social and behavioral sciences more broadly. On the one hand, most political psychologists agree today that emotions play a key role in driving individuals and groups toward violent conflict, but also toward de-escalation processes. At the same time, both from a conceptual and a methodological

perspective, there is still a long way to go before we can achieve at least part of the potential embedded in studying emotional processes in conflict situations.

We have suggested in the current chapter that to address that gap, an integrative approach should be adopted, one that brings together a descriptive view on the role of emotions in conflicts, with a more interventionist approach on the ways through which emotional change can promote support for peaceful resolution of such conflicts. The current chapter reviewed several steps made in recent years to promote such an integrative approach. For example, as we reviewed in the current chapter, scholars in the field have managed to develop a much more nuanced view of the nature and implications of discrete group-level emotions on conflict related policies and behaviors. After more than two decades on intensive research, empirical work from various contexts on prolonged conflicts have allowed us to more deeply understand which situations would give rise to which group-level emotions and among which individuals. These studies also enabled us to pinpoint the discrete emotions that constitute catalysts or barriers to various conflict related processes (e.g., support for compromises for peace, humanitarian aid, intergroup interaction and negotiation). We illustrate that what seem to be considered positive emotions might be at times destructive to conflict resolution, and vice versa regarding negative emotions that at times may be constructive. Finally, in the last decade, there is some work showing quite promising indications regarding the impact of effective emotion regulation processes as tools for conflict transformation.

However, as we suggested, more work is needed and, as we see it, political psychologists should utilize progress made in other domains of research and society to deepen our understanding of emotional processes in conflicts. For example, social media provides a fertile ground to the study of emotional processes in groups in general and in conflicts more specifically (Goldenberg & Gross, 2020). Also, big data science, coupled with social media targeting, enables a more personalized approach to the way individuals are driven by emotions in conflict situations, as well as to the way different emotion regulation efforts can differently influence different individuals according to their backgrounds, personality characteristics, or ideologies (Halperin & Schori-Eyal, 2020).

Future work should also go beyond the emotional “immediate suspects,” taking into account other group-based emotions, such as (but not limited to) *schadenfreude*, admiration, and contempt. It should also study other emotion regulation strategies besides cognitive reappraisal, while taking into account more seriously the aspects unique to intergroup conflicts such as power relations, traumatic experiences, and identity complexity. Finally, from a methodological point of view, the integration of neurophysiological studies, on the one hand with large scale field experiments, on the other hand, seem like the next step in the study of emotions in conflict.
